I. INTRODUCTION

This chapter introduces the work performed by Economic Strategies Group, and its sub-contractors, for the MAG Socioeconomic Models Enhancement Project. The project was performed over a 15-month period from November, 1992 through January, 1994. Most of the data collection was performed during the first half of 1993, and thus the databases should be assumed to be current as of that time period.

The scope of work for the project included nine tasks ranging from background research, to the development of databases, to the creation of projection methodologies. In all, the goal of the project was to develop information and methodologies that could be used to supplement MAG's socioeconomic modeling process. This includes both estimates of current conditions, as well as projections of future conditions.

The sections that follow briefly describe the work performed for each task. These descriptions include the goals of each task, a guide to the documentation for each task, and a listing of the products developed. MAG member agencies were given an opportunity to review the data produced for this project.

Task 1: Refine the Scope of Work

The project was of sufficient size and scope that it was necessary to finalize certain elements of the work scope as the beginning task of the project. This task resulted in the scope of work described below.

Task 2: Background Information

The purpose of this task was two fold. The first goal was to review recent legislation that may have an impact on the methodologies used by MAG to perform socioeconomic estimates and projections. The second goal was to research alternative methods for performing some of the other tasks of the Socioeconomic Models Enhancement project. Specifically, research was performed on methods of estimating and projecting employment, and methods for estimating and projecting special populations. This research is documented in Chapter II of this report.

Task 3: Geographic Boundaries

This task contained two primary work items. The first was to recommend and implement changes in Traffic Analysis Zone (TAZ) boundaries to be consistent with Census geography, particularly at the Census Tract level. The second, work item was to profile existing and potential development in each of the 141 Regional Analysis Zones (RAZs). These work items are documented in Chapter III of this report. This task resulted in four specific data/model related products including:

- Revised TAZ boundary file in Arc/Info format;
- A Census Block to TAZ correlation file;
- A revised TAZ to RAZ correlation file; and
- A book profiling existing and potential development in each RAZ (available from MAG).

Task 4: County-level Projections

This task focused on deriving county-level projections of non-resident population, resident group quarters population, selected household income characteristics, and selected economic characteristics. The issue is that the County-level projections prepared by the State of Arizona do not contain this detail for socioeconomic variables. Work on each of these variables is described in detail in Chapter IV of this report. In short, ESG prepared projections for five year intervals from 1995 to 2040 of:

- Non-resident population (seasonal and transient);
- Resident group quarters population; and
- Retirement population by income quintile.

ESG also prepared estimates of detailed socioeconomic characteristics for 1990 based on the Census Public-Use Microdata Sample (PUMS). These included:

- Workers per household by income quintal;
- Population per household by income quintal; and
- Unemployment rates by economic sector.

Task 5: Employment Database

As its name suggests, this task's primary goal was to update and extend the **database of major employers** maintained by MAG for use in its employment estimates. The goal was to include all employers with more than 50 employees at a single site. The database was created by merging employer data purchased from Claritas NPDC, and data collected from other primary and secondary sources, with Trip Reduction and other databases maintained by MAG. The resulting database included nearly half of all employment in Maricopa County.

A secondary goal of this task was to develop a Standard Industrial Classification (SIC) to MAG-sector (land use) correlation matrix for employment. The problem has been that County-level estimates and projections of employment are reported by industry (through SIC codes), but that small-area estimates and projections must be driven by land use. To develop a correlation matrix, ESG used national employment data from the Bureau of Labor Statistics which cross-tabulates employment by industry and occupation. Using this data, and assumptions about the land uses where persons in a given occupation are likely to work, it was possible to derive an industry to land use correlation matrix (Chapter V, Table V-4).

Both the tasks reviewed above are documented in Chapter V of this report. Products delivered as result of the task included the updated Employment Database, and the SIC-to-MAG sector correlation matrix.

Task 6: Parcel Based Database

The goal of this task was to update MAG's Parcel Based Database. The database contains a record for every parcel of land in Maricopa County as recorded by the Maricopa County Assessor's office. The records include such information as land use, acreage, square footage of commercial buildings, type of residential buildings, and the full cash values of land and improvements. Each parcel in the database is geocoded (identified by its location on a map), which makes this information very useful in preparing small-area estimates and projections.

Many of the parcels were geocoded based on address information provided by the County Assessor. However, for many other parcels it was necessary to locate the parcels based on the book-map containing the particular parcel. This meant that an accurate book-map map had to be created.

Chapter VI of this report documents the process undertaken to update the database, and create the new book-map map. Products produced by the task include the updated Parcel Based database containing nearly 900,000 parcels, and a book-map map transmitted as an Arc/Info boundary file.

Task 7: Special Population Groups

The purpose of this task was to examine alternative methodologies for creating small-area estimates and projections of special population groups. The special population groups involved included the same set for which county-level forecasts were prepared in Task 4 of this project, namely:

- Non-resident seasonal population;
- Non-resident transient population; and
- Resident group quarters population.

It was desired that a method be found to produce estimates and projections of these population groups at the RAZ level of geography. To implement the estimates, ESG performed an inventory of facilities and sites that house people in each of these groups. This inventory was transmitted to MAG as one deliverable of this task.

For projections, the goal was to examine alternative methods for allocating county-level growth in each population group to RAZs. The projections developed, and provided in Chapter VII of this report, are meant as illustrations only. The key product of this part of the task was the examination of how these group may be, and may not be, projected.

Task 8: Other Data Requirements

This task brings together three data collection activities also needed by MAG to enhance its socioeconomic models. First is an update of the Planned and Proposed Development database. This database includes a list of all active (under construction), planned, and proposed large scale development projects in Maricopa County. The list of projects was assembled using information purchased from Canyon Research, provided by the Maricopa County Planning Department, and obtained through published articles and interviews.

The second product of this task focused on redevelopment areas around Maricopa County. This information was obtained directly from city planning departments through interviews conducted by ESG. Information on the area included, and the expected and/or desired land use was obtained.

For both development and redevelopment, the information was coded into a database, and the "footprint" of each project was mapped.

The final item included in Other Data Requirements was an estimate of land values in Maricopa County by book-map area. Full cash value of land information from the Parcel Based database, developed in Task 6, was aggregated to find the total land value in each book-map. These aggregated values were then divided by the total land area of each book-map to estimate average land values per acre.

Chapter VIII of this report documents the process used to create each of the data products listed above, and shows the contents of the databases created.

Task 9: Final Documentation

This task includes all final documentation for the project. This includes working papers for each of Tasks 2 through 8. These working papers provide the most detailed information about the work done for each task, and contain the most printed detail of the results. The task also included creation of this report, and an executive summary of this report, also available from MAG.

Please note that while every effort has been made to provide the most current and accurate information available, MAG, ESG and its subcontractors make no warranty, express or implied, as to its accuracy and expressly disclaims liability for the accuracy thereof. This work is part of the process necessary to support a sophisticated socioeconomic modeling program like MAG's, and by its nature will continue to need updating and refinement.

II. BACKGROUND INFORMATION

1.0 REVIEW OF RECENT LEGISLATIVE SOCIOECONOMIC MODELING IMPLICATIONS — COUNCILS OF GOVERNMENTS SURVEY

Telephone calls to ten selected COG's (Councils of Governments) revealed certain commonalities of approach and opinion while other questions prompted widely divergent responses. Figure 1 summarizes the interviews in a matrix of COG responses to each of seven questions. The COG's contacted included:

- Bay Area (ABAG and MTC)
- Chicago (CATS and NEIPC)
- Dallas (NCTCOG)
- Denver (DRCOG)
- Houston (HGAC)
- Los Angeles (SCAG)
- Minneapolis/St. Paul (TCAG)
- Portland
- San Diego (SANDAG)
- Seattle (PSRC)

There is a consensus about the approach to be taken in response to recent legislation including I.S.T.E.A. and Clean Air Act Amendments. A more comprehensive consideration of land use planning scenarios with transportation options is required. In its simplest form this is a comparison of the present (base year-no build) with some future situation (target year-build). However the base year used by the COG's varies from 1990 to 1993 and the target year ranges from 1996 to 2040.

The DRAM/EMPAL land use planning model is the common vehicle used by most of regions that were contacted. Some COG's have used this model for several years while others, like Houston, have recently acquired it. Greater experience with the model reveals less satisfaction with the output of the model, and regions like Los Angeles and Portland anticipate enhancements to address their concerns. Chicago, Denver and Minneapolis/St. Paul do not use any land use model but employ other routines such as multiple regression analysis, for the same employment and population allocation purposes. In some instances, the basic DRAM/EMPAL model is supplemented by other models or routines.

Interaction or integration with other models is achieved by using the output of the land use model as input to the transportation model. This is common practice. Many regions believed that this iterative process satisfies I.S.T.E.A. and Clean Air Act Amendments objectives. Additional enhancements consist of changes to the transportation model or modifying land use and socioeconomic data input to DRAM/EMPAL with the output of the transportation model.

Suggestions for modifying the land use model include:

- Land cost
- Land availability
- Development costs
- Indicators for amenities
- Housing prices

While transportation adjustments include:

- Vehicle occupancy
- Vehicle ownership
- Modal split
- Trip reduction

A fully integrated land use and transportation process will not be completed in the near-term for most regions. The exceptions are Los Angeles and Portland, which are likely to achieve an integrated process in 1993.

The common review period is every five years. The technical review accounts for two to three years of this timeframe and the policy review for the remaining two years.

In all instances, the regions are given regional or county control figures by their state governments. In five of six regions, employment-driven control projections are used. California uses a process that includes both an economic employment-driven model and also a demographic model using the cohort survival methodology. Adjustments are made to the output. Seattle and Chicago also use an employment-driven forecast. In Portland, the State of Oregon used a population-driven approach in the latest generation of data. The view taken is that such an approach is more relevant in this region because of the high level of in-migration from California and national trends toward an aging population structure.

Most regions felt that their current planning process adequately addresses the requirement of developing land use scenarios for alternative transportation options.

In order to develop land use scenarios, most regions use a fairly standard planning process. Alternatives are developed based on various growth assumptions arising from the agency's analysis of growth, change and trends in the study area. Typically, the base year is the current or near-current year and is then used as the no-build (or do-nothing) situation.

These land use alternatives are then projected forward in a single or series of project phases to the end or target date of the study. The timeframe varies from city to city. The target date is the build scenario. The implications are then reviewed as to economic impact, and the socioeconomic implications and weighed against the regional/agency goals and policies.

In essence, there is no firm rule as to the approach to be taken. Most of the respondents follow the same or similar approach that incorporates ISTEA factors, although they vary as to the details of base year and target year. The major departure from standard planning process is the emphasis on transportation issues to be studied as an integral part of the whole.

2.2 CLEAN AIR ACT AMENDMENTS 1990

The Clean Air Act Amendments (CAAA) were reviewed from the document supplied by Maricopa Association of Governments entitled "Summary of the Clean Air Act Amendments of 1990" dated October 24, 1990.

The Environmental Protection Agency has designated the Maricopa County planning area as a Moderate Non-Attainment Area for Carbon Monoxide and Ozone. As such the CAAA requires that the MPO prepare a State Implementation Plan (SIP) to show how attainment of the national air quality standards are to be met and maintained. Socioeconomic implications arise from the programs incorporated in the SIP, such as the vehicle inspection and maintenance program.

Other requirements of CAAA include:

- An emissions inventory;
- A forecast of vehicle miles travelled if the non-attainment value exceeds 12.7 parts per million (ppm);
- Contingency measures.

In addition, the CAAA directs the EPA to promulgate regulations concerning:

- Extending inspection and maintenance programs with stricter emission controls;
- Use of oxygenated fuels;
- Use of reformulated fuels;
- Withdrawal of leaded fuels for highway use;
- Apply emission control of particulate matter to urban buses that are diesel fueled.

These regulations may have future socioeconomic impacts that may result in increased costs of vehicle ownership, increased demand for public transit and increased cost of public transit.

2.3 FEDERAL IMPLEMENTATION PLAN FOR MARICOPA COUNTY ENVIRONMENTAL PROTECTION AGENCY 40 CFR. BART 52 (FRL-3901-3)

This document contains the Implementation Plan for the non-attainment areas for Carbon Monoxide in Maricopa and Pima Counties. The document was reviewed for socioeconomic implications. The findings are set out below.

<u>PAGE</u>	<u>DESCRIPTION</u>
19	In the review of fifty-five alternative measures for congestion management, one of the criteria used to evaluate alternatives was socioeconomic impact.
43	Cost of the Promulgated Control Measures; EPA estimates that there will be an increase in the price of gasoline.
75	Summary, Results of Candidate (Measure) Screening; potential candidates include: <ul style="list-style-type: none"> • More stringent Travel Reduction Program, • Financial incentives to employees in lieu of parking space, • Preferential parking for car/van pools, • Free transit passes to employees, • Alternative workhours/weeks, • Telecommuting, • Teleconferencing, • Encourage bicycle use, • Encourage pedestrian travel, • Conversion of vehicle fleets to alternative fuels, • Retrofit pre-1975 vehicles with catalytic converters, • Increase standards, remove exemptions, and expand inspection and maintenance programs statewide.

All of these candidate measures may have land use planning and socioeconomic implications.

3.0 ESTIMATING & PROJECTING SPECIAL POPULATIONS

This section is the result of a review of recent literature and approaches for alternative methodologies, current and past implementations, and data requirements of estimating and projecting special populations. Interviews were conducted with key informants from various government agencies including state governments, councils of government, universities, utilities, and private consultants.

"Special Populations" are defined to include: visitors, seasonal populations, transient populations, and group quarters populations. The purpose of this review is to assess the currently used and accepted approaches as a first step in developing the methodology to be implemented in estimating and projecting special populations in Maricopa County.

Following a brief section on the definition of terms used in this research, the report is divided into two chapters. Chapter 2 presents literature reviews and key informant interviews relative to **County-level** estimates and projections, while Chapter 3 focuses on **sub-county** areas.

Definitions. Generally, visitors who stay at least one night are included in a methodology to estimate temporary residents due to the demand they place on infrastructure and local services. For some research problems, the minimum length of stay for temporary residents may be increased from one night to several weeks or months. It is important to define the

objective of the seasonal resident as job-related or vacation- or retirement-related because of the different impact of these groups have on the local community.¹

The group definitions used here include:

- ***Seasonal Population*** - That portion of the nonresident population that resides within the area at certain times of the year for more than two weeks.²
- ***Transient Population*** - That portion of the nonresident population that resides in the area for less than two weeks and who reside in hotel, motel or RV housing units.³ Persons staying in private homes or apartments may be added to this definition.

Transient and seasonal populations may also include extraordinary activities like mineral exploration crews, movie film crews, auto test crews, etc.⁴ They also usually include tourists, business people, snowbirds, seasonal workers and undocumented persons. Some of the people in the last three categories would be included in group quarters population.

- ***Group Quarters Population*** - That portion of the resident population that resides in a non-household living quarters such as institutions, congregate care facilities or college dormitories (institutional or non-institutional); Group Quarters are any living arrangement other than households. This includes institutions such as mental hospitals, homes for the aged, prisons, etc., plus other quarters containing 10 or more persons where 9 are unrelated to the person in charge, or where there is no person in charge. Such quarters are most commonly found in sole-purpose facilities, but may also be located in a house or apartment used as a rooming house or occupied on a partnership basis.⁵ Homeless persons are also defined by the Census Bureau to be in group quarters.

3.1 COUNTY LEVEL ESTIMATES & PROJECTIONS

This section provides literature reviews and key informant interviews on the subject of county-level estimates and projections of special populations. Each section analyzes a different component of special population.

3.1.1 Visitors

Planning Information Corp., "Topics in Economic-Demographic Monitoring," July 13, 1992.

In this article an attempt was made to incorporate current data into techniques of visitor counts for Nye County, Nevada. The primary data included motor vehicle traffic statistics and lodging tax revenues. Vehicles are counted by the Nevada Department of Transportation (NDOT) and the results are converted to a consistent measure of year-round traffic volume called average daily traffic (ADT). NDOT conducts occupancy studies at various points in the state and calculates average occupancy levels for types of roads and classes of vehicles. NDOT also takes count of the ratio of trucks to passenger vehicles and of in-state to out-of-state licenses. NDOT statistics can be used to estimate the number of occupants in out-of-state vehicles, a number which may be used as a proxy for the number of tourist travelers on Nye County roads. This estimate includes tourist travelers in personal vehicles and excludes tourist travelers on commercial and tour buses.

Origin and Destination (O&D) studies reveal where people are going and other trip characteristics, information which adds dimension to the ADT and occupancy data. The studies contact traffic in one or both directions, at one or a number of sites, surveying all vehicles and distinguishing among trucks, RVs and passenger cars. A survey which includes trip origin and destination, number of passengers, and planned length of stay is answered by all motorists.

Lodging tax revenue records provide another basic source about visitors who stay overnight. The basic state lodging tax rate can be used as a generally reliable indicator of lodging revenues at motels and RV parks. The gross revenue is estimated by dividing reported tax revenues by the tax rate to arrive at gross revenue. Therefore Nye County is able to estimate the average revenue per room/RV night by dividing estimated revenue by an average room rate or space rental factor. If the average number of persons staying in a room/RV space per night is determined through further survey, the number of visitors using overnight accommodations may be estimated.

Behavior Research Center, "Metro Phoenix Visitor Study, Topline Summary for 2nd Reporting Period: May - July 1992," August, 1992.

This Metro Phoenix Visitor Study includes intercept interviews conducted with Metro Phoenix visitors at Sky Harbor International Airport, a varied cross-section of area attractions and lodging facilities, and also include telephone interviews conducted with out of area residents who requested tourism information from Valley visitor bureaus.

- The intercept surveys at Sky Harbor and selected areas included many visitor demographics: age, income, place of residence, travel party

configuration, percent of party by age group, length of stay, accommodation by category, travel mode, communities visited, past and future visitation habits, and reason for current visit.

- The phone interviews with people requesting tourist information contained much the same data for persons who had visited the area or who were planning to visit the area.

This report, one of four quarters to be surveyed, should provide good base data for estimating business and pleasure travelers who do not stay in private homes.

Stanley Smith, "Toward a Methodology for Estimating Temporary Residents," Journal of the American Statistical Association, June, 1989.

Smith delineates a method of using number of visitors multiplied by average length of stay to estimate "visitor days." Smith also states that dividing the visitor days by a factor of 365 will yield "visitor years," a measure that can be used to combine estimates for temporary and permanent residents.

Some residents come to an area for production purposes (jobs), and others come for consumption purposes (vacation). The distinction between the two is very important because the impacts of the user groups will differ considerably. In this model there are four distinct types of temporary residents: daytime production (commuters), daytime consumption, overnight production, and overnight consumption.

The major source of data on daytime commuters is the decennial census of the United States, Census of Population and Housing. This census collects journey-to-work data for all commuters working outside their metro areas. The main drawback of this data is the collection period of once every ten years.

Overnight visitors can be tracked by total sales tax or sales tax collected from commercial lodging facilities. The latter measure only estimates the number of temporary residents in hotels and motels, not permanent housing. However sales tax can be used to measure all types of seasonal populations. Sales tax data is adjusted to account for economic conditions and growth in permanent population. Using the lowest adjusted month as a baseline, and assuming that there are no visitors at that time, it can be compared to the highest month. This comparison will yield the sales tax increases due to visitation by temporary residents. Using an average expenditure per visitor per day the number of visitor days can be estimated. Converting the visitor days to visitor years will estimate a transient population. The major drawback to this method is the inability to differentiate between the day and night seasonal populations, the assumption that no visitors are present in the lowest adjusted month, and the averages which must be used to derive visitor days and years.

Key Informant Interview: Lin Zane, Director of the Hawaii State Department of Business, October 17, 1992.

The state of Hawaii provides a questionnaire to all persons on airline flights with a destination to one of the islands. This questionnaire is used to determine length of stay, places people will visit, expenditures while visiting, type of lodging, etc. Lin Zane stated that

this survey works well for Hawaii because of geographical reasons, but would miss many people entering an area such as Maricopa County.

3.1.2 Seasonal Populations

Key Informant Interview: Steve Murdock, State Data Center at Texas A&M University, October 28, 1992.

To estimate the "snowbird" population, month to month changes in utilities may prove useful. Information on whether the snowbirds disconnect their utilities and on household size may be obtained by a telephone survey targeting key telephone exchanges provided from the telephone company. Also, legislation regarding such areas as homestead tax exemptions, which usually have a six-month residency requirement, may be useful. However, in Arizona homestead exemption (a form of property tax credit) is restricted to widows, widowers, and the disabled, and is not, therefore, useful for MAG's purposes.

T. Hogan and S. Happel, "1991-92 Winter Residents Help Sustain AZ Economy," Arizona Business, June, 1992.

This article describes the outcome of a series of questionnaires that were mailed to owners and managers of RV/travel trailer/mobile home parks in an eleven county study area in Arizona. The questionnaires asked about numbers of mobile homes, travel trailer, and RV spaces, occupancy rates, and number of winter residents in the first week of February 1992. Occupancy rates and winter resident proportions were calculated from the information supplied by responding parks. For the non-responding parks, counts of the number of mobile home and travel trailer/RV spaces from the survey's data base were combined with the computed ratios to estimate occupancy rates and proportions of spaces occupied by winter residents of the non-responding parks. An average of two persons per vehicle was assumed, as shown in past research. These imputed data were then merged with the census information to produce estimates of the numbers of winter residents living in mobile home/travel trailer/RV parks during the first week of February 1992.

Surveys of parks conducted during the past two winter seasons by the Center for Business Research discovered that approximately 60% of the seasonal population were living in mobile homes/travel trailers/RV's. Also, information from the ASU park survey is available on a valleywide basis for each season since 1985-86, making it possible to examine trends relating to the area's winter seasonal population.

These data can be used to make base year estimates of seasonal population in RV/travel trailer and mobile homes in Maricopa County.

Maricopa Association of Governments, "Household Survey of Metro Phoenix," August, 1988.

The Household Survey of Metro Phoenix contains the results of a phone survey of households in metropolitan Phoenix with the purpose of obtaining statistically valid values for household size by type of residential dwelling unit.

The values for household size are used to establish total population for Maricopa County and the geographic sub-regions used by the Maricopa Association of Governments for

transportation modeling and planning. A secondary purpose of the survey was to obtain demographic characteristics such as winter visitors in private homes to estimate variables in the 1988-89 Population and Socioeconomic Database Update Study.

The survey defined a seasonal resident as a visitor staying for more than two weeks during the winter tourists winter season: the period between September 1, 1987 and May 1, 1988. The survey included the estimated number of seasonal residents living in private homes in Maricopa County during the 1987-88 winter season. The survey also included the length of stay, the number of visitor weeks spent in private homes, and seasonal population equivalent of the visitors added to the County during the visiting season.

Planning Information Corp., "Topics in Economic-Demographic Monitoring" July 13, 1992
Pahrump, Nevada was the location for a survey which estimated "snowbird" population characteristics, including age, season to visit, duration of stay, where expenditures were made, and activities of the snowbirds.

The definition of a snowbird for this study is a person who, because of colder weather elsewhere, migrates from their usual place of residence to Nye County (Pahrump, Nevada) for three months or longer. The study assumed that snowbirds stay in one of five types of places: 1) RV or travel trailer parked in a commercial park, 2) RV or travel trailer parked on a private lot, 3) permanent housing (apartment, home, etc.), 4) a motel unit, 5) the residence of friends or family.

The number of snowbirds in RV's were determined by counting the RV's on private and commercial lots and multiplying by two persons per RV. The survey assumes that the snowbird population staying in motels is about 15% to 20% of the RV population. The survey did not address snowbirds in their own homes or staying with friends or relatives.

The survey determined that the visiting season started in the end of September and ended around the end of April. Some of the reasons given for the end of the season were the April 15th deadline for income tax filing and a return to warmer weather in the original place of residence.

John Semmens, "Possible Methods for Measuring Seasonal Population," Memo Presented to the Arizona State Population Technical Advisory Committee (POPTAC) on June 4, 1990.

The memo outlines many sources of data that could be used to estimate seasonal populations. Indicators such as consumption levels of basic goods, water usage, electric usage, and food consumption may all be used to measure populations.

Using water usage as an indicator of population size would require measuring the water use for a sampling of households to determine average water use per household or per capita. The average usage level could then be applied to total water consumption at several points during the study year to estimate seasonal population. There would have to be controls to account for changes in weather. Electricity usage could be tracked in much the same way.

Food consumption could be another measure to estimate population size. Milk was suggested as a food which could provide a suitable proxy for population size. To determine a base measure for gallons of milk per person it is necessary to start with a year where resident population is known. This base year is then applied to milk consumption figures for future years to determine population size. The main drawbacks of milk as a measure

are price fluctuations and changes in age structure that could affect the overall rate of consumption per capita over time.

Coopers and Lybrand Report to Maricopa Association of Governments for the Department of Water Resources, "Literature Search and Data Collection for Nonresident Population," January 31, 1991.

Prior to 1989 the Department of Water Resources used a methodology based on vacant units and "zero delivery months" to determine seasonally adjusted population. The total full-time equivalent number of vacant units is calculated separately for single family and multi family housing units. The total number of vacant months is calculated based on a survey by the water service provider. The number of vacant months is used to calculate average vacant units. Average annual single family vacant units can be divided by total single family units to determine the vacancy rate.

The total number of zero delivery months is then calculated from billing records. Delivery of less than 748 gallons of water to a single family unit or other detached housing unit with outdoor landscaping is defined as a "zero delivery month." Zero delivery months were then converted into average annual zero deliveries. The number of vacant units based on the survey is compared to the number of vacant units based on zero deliveries to determine true vacancy rate. If the number of vacant units based on zero deliveries is significantly different than the survey amount, indicating a large seasonal population, zero delivery months are used to calculate the final vacancy rate.

The vacancy rate for multifamily units is calculated based on a survey sample from apartment managers in the water service area. The annual average vacancy rate for multifamily units by water service area is also calculated based on housing market research from an outside source. The most credible vacancy rate of the two is multiplied by the total number of multifamily units to determine the number of vacant units on an FTE basis. The population per housing unit measures are applied separately to the number of occupied single and multifamily to determine the total service area population. For single family units, a full time equivalent number of vacant units is calculated based on the number of vacant unit months. The number of vacant unit months is determined using the method indicating the larger seasonal population of the following methods: a survey by the water service provider and by the number of unit months with water usage of less than 748 gallons or "zero delivery." All water service providers have data available on water usage by meter month. Because standards of usage vary greatly between communities it is possible to utilize data from the water service providers to estimate seasonal populations, as long as each community is analyzed individually.

Timothy Hogan, "Determinants of the Seasonal Migration of the Elderly to Sunbelt States, Research on Aging," March, 1987.

This article presents a regression that attempts to estimate seasonal population using independent variables that include population over 65 in origin state, distance from the destination state, income in the origin state, climate of the destination state, relative cost of living in destination state, and a dummy variable for migration from east/west states. The statistically significant variables of the Arizona model include January temperature differential, the size of the elderly population, and income level in the origin state, and the east/west dummy variable. The dummy variable is used to account for the negative correlation associated with certain eastern states migrating to Florida, not Arizona. When

the east/west dummy variable is removed from the model distance to Arizona from the origin state showed strong negative correlation to total migration.

Ronald Gunderson, "A Method for Estimating the Seasonal Population in Rural Regions: A Case Study of Northern Arizona," Economic Development Review, Spring 1989.

A method for measuring seasonal population in a region included sampling procedures to estimate average and peak number of visitors. Seasonal population in this article is defined as visitors who spend at least one night in the areas including: persons who own second homes, persons staying in motels and cabins, persons staying in campgrounds, and attendance at children's summer camps. Visitors staying with friends or relatives are excluded from this study.

If a property is assessed at 10 percent of the market value, indicating residential use, the address of the owner is checked. If the address of the owner is listed outside the county the home is assumed to be a second home. (This methodology may have caused some under counting due to some units being owned by local residents for use as second homes.) Between five and ten percent of the second homes were then surveyed to determine the type of unit, what portion of the year the unit was occupied, whether the home was rented out at any time during the year and how long the resident had owned the property. The total number of second homes was estimated from the survey results.

Key Informant Interview: Bill Lenard, Broward County, Florida, November 2, 1992.

An undercount exists in the number of vacant seasonal or occasionally occupied dwelling units listed in the Census. There are a large number of garages and spare rooms being rented seasonally which are not reported. People hesitate to report these because of zoning or taxation laws. Some of the people counted as seasonal population are actually full-time residents, but they do not want to risk losing their Canadian citizenship or benefits by making this known.

Key Informant Interview: Karen Wolf, Salt River Project, Phoenix, Arizona, November 3, 1992; May, 5, 1993.

In the latter part of 1992, Salt River Project (SRP) conducted research to determine if seasonal visitors typically leave on or disconnect their service in the summer. However, SRP has instituted a program where seasonal residents can have utilities placed on inactive status without actually being disconnected. For this reason, it is difficult to separate and measure activity of winter visitor accounts.

3.1.3 Transient Populations

Key Informant Interview: David Taylor, Planning Coordinator for the City of Tucson-Advanced Planning Division, October 28, 1992.

Part of the homeless population may be classified as either transient or seasonal. Homebase, an advocacy group for the homeless may be able to provide estimates. The City of Tucson, Arizona estimates that for every bed available in a shelter during the winter

season, there are two more homeless people living in alleys, washes, etc. Because the homeless have such a wide variety of demographic characteristics, this may be the only way to count them. This suggests that interviews with homeless providers in Maricopa County may be a possible methodology for estimating the number of base year homeless.

3.1.4 Group Quarters Populations

Key Informant Interview: Dan Shay, Demographic Research Unit for the California Department of Finance, October 27, 1992.

In California, group quarters are surveyed by the state, which keeps a list of names and addresses. They use the most recent census as a bench mark and ask local jurisdictions to survey the facilities and list changes. The state is responsible for surveying the federal facilities.

Key Informant Interview: Jim Westcott, Department of Local Affairs, Colorado Division of Local Governments, October 27, 1992.

Only a portion of college students live in group quarters or dormitories. Students over 25 years, who may be permanent residents, should be distinguished from groups that come into the university town and stay for two to four years and then leave. This definition by the State of Colorado does not appear to match the U.S. Census Bureau definition of "seasonal" population. For the Census Bureau, college students are included as part of the "resident" population and are distinguished to be group quarters population if they live in dormitories.

Similar counties without a university were looked at as a control group for university student age categories. The percent of the total above the control group are considered to be temporary residents. The temporary college population is not added to the permanent population figures, except for those students over 25 years who are actually permanent residents.

Colorado Division of Local Governments, Department of Local Affairs, "Colorado Population Estimates and Projections, 1990-2015," August, 1991.

For several types of group quarters residents (college students, state prison inmates, and military personnel), the size and age-sex composition of these populations are projected separately based on their special characteristics derived from census and other sources. They are not subject to the mortality and fertility schedules as the same cohort component model, nor are they subject to the migration assumptions projected by the econometric model.

3.2 SUBCOUNTY LEVEL ESTIMATES & PROJECTIONS

This section contains literature reviews and key informant interviews on the subject of estimating and projecting special population groups at the subcounty level. This section analyzes a different component of special population.

3.2.1 Visitors

City of Scottsdale, Office of Economic Development, "The Scottsdale/Paradise Valley Tourism Study, Part 2: Visitor Statistics," January, 1992.

There are four resort "cores" with services and amenities geared for the short term business visitor, the conference and convention visitor, large business groups, and independent leisure travelers.

The first step is to determine the total number of visitors and visitor nights by category. The total number of rooms in each subarea (City of Scottsdale, Town of Paradise Valley, and the areas within the market area) is multiplied by 365 days per year and the average annual occupancy rate to determine the total number of room nights that are occupied. To determine the total number of visitors the number of occupied room nights are multiplied by the average number of persons per room to arrive at a figure for total visitor nights (one visitor night equals one person staying one night). There is no accurate way to measure day visitors. This study took the total estimate for visitors to Metro Phoenix, subtracted out the total number of hotel, seasonal, and houseguest visitors to the Scottsdale/Paradise Valley market area and assumed that out of the remaining balance that Scottsdale captures 40% as day visitors. The figure for total number of seasonal visitors and houseguests was taken from Larking Marketing and Research "The Scope and Impact of The Scottsdale AZ Seasonal Resident," May, 1985, and updated by 4% annually to reflect 1992 counts.

The City of Key West Comprehensive Plan, "Population Estimates and Projections," November, 1991.

For purposes of the study, visitors are defined as people who visit Key West for periods of less than three months at hotels, guest houses, boarding houses or campgrounds, rental homes or condominiums, or stay with friends and relatives.

For the first phase of the estimates, the number of overnight tourists lodging at hotel/motels was calculated. The formula used to calculate the number of overnight tourists lodging in hotel/motel accommodations was: $(\# \text{ hotel/motel units}) \times (\# \text{ persons per party}) \times (\% \text{ occupancy rate})$. Information on hotel/motel units was obtained from the City of Key West. The Department of Commerce, Division of Tourism Visitor Profile provided information on the average party size of visitors and hotel/motel occupancy rates.

For the second phase of calculating the overnight visitor population, the ratio of overnight tourists who actually lodge at a given hotel/motel to the total lodging accommodations actually used was recorded. The number of overnight tourists who lodged at a given hotel/motel on any one day (answer to phase one above) was divided by the percentage of overnight tourists that actually lodge at hotel/motel accommodations in order to determine the total estimated tourist population on any one day.

3.2.2 Seasonal

Metro-Dade Planning Department, "Dade County Florida, Seasonal Population," October, 1987.

The planning department in Dade County produces annual estimates of seasonal population by subarea. The seasonal population includes any person who stays at least one night in the county and includes: seasonal residents who occupy a previously vacant housing unit, visitors in hotels and motels, and visitors who stay with friends or relatives.

A number of different factors were considered as indicators of the size of the seasonal population including: summaries of residential electric customers, monthly water and sewer volumes, summaries of gasoline sales, monthly garbage pickup volumes, resort and tourist tax collections, and traffic volumes on selected arterials.

The methodology which was used was based on the rise and fall in residential electric usage for customers. A peak occurred in February/March at the height of the tourists season which could be compared to a corresponding drop in electric customers in August/September. To adjust for undercounting due to seasonally vacant homes where the electricity was left on in the summer, electric customer data was benched to the 1980 Census data on nonresidential homes. The calculation of nonresident households based on the Census included "vacant units held for occasional use," "vacant seasonal units," and "vacant other" units. The adjusted seasonal number was converted to total seasonal population by assuming a 95 percent occupancy rate and an average population per dwelling unit of 2.2 persons.

Susan Krug Fieldman, "Forecasting a Seasonal Population," Business Economics, July, 1988.

A method for estimating trends in seasonal population was based on a case study of Salt River Project customers in Phoenix. The seasonal pattern of residential electric customers was used as a proxy for seasonal residents. The total number of customers in the peak of the tourist season was compared to the low in the summer months, adjusting for growth in permanent housing. The seasonal difference in electric hookups was used as a dependent variable in a regression model. The methodology does not exclude winter only residents who do not disconnect their electricity in the summer. The independent variables which were found to be significant in seasonal migration were population over 65 years, temperature severity, and the Canadian dollar exchange rates.

3.2.3 Group Quarters Population

N. Rives and W. Serow, "Introduction to Applied Demography-Data Sources and Estimation Techniques," 1984.

A count of the number of residents of each group quarters facility in the study area is needed on or about the date of the population estimate. Unless this information is routinely available, the data will have to be collected through inquiries. The authors recommend starting with institutions, such as prisons and health facilities, for they are obvious sources and may account for a significant proportion of the group quarters total. Census Bureau regional offices can provide information on boundary locations, as well as determine whether

a particular facility qualifies as a "group quarters" institution under Census Bureau rules. Non-institutional group quarters population includes the population found in college dormitories, military barracks, halfway houses, boarding houses, and communes. The Census Bureau generally limits the category to living quarters occupied by at least ten persons not related to the person who owns or rents the quarters. It is best to begin estimating the size of non-institutional group quarters population by contacting all colleges and universities and military installations within the boundaries of the study area. If trying to contact group quarters facilities does not yield satisfactory results, then the next best approach is to consult the most recent census.

4.0 REVIEW OF RECENT LITERATURE AND APPROACHES FOR ALTERNATIVE METHODS OF ESTIMATING & PROJECTING EMPLOYMENT

4.1 LITERATURE REVIEW

A due diligence effort was made to research recent information on small area estimates and control total projections of employment. There is very little information on either subject; moreover, all articles are quite old (i.e., more than fifteen years). Although there were some recent articles on county-level projections, these dealt with demographic forecasting techniques, not economic forecasting techniques. Based on the literature review, more emphasis was based on obtaining information from direct interviews with other regions.

4.2 KEY EMPLOYMENT INTERVIEWS

Key informant interviews with eight Councils of Governments were conducted to review the development of small area estimates and control total projections of employment. The information collected is presented in the following figures:

- (1) Figure II-2 lists the contacts;
- (2) Figure II-3 summarizes the approach for small (e.g., traffic analysis zone, regional analysis zone) area estimates; and
- (3) Figure II-4 summarizes the frequency and approach for updating control total projections.

FIGURE II-3

SMALL AREA EMPLOYMENT ESTIMATION TECHNIQUES BY SELECTED COUNCILS OF GOVERNMENT

QUESTION	BAY AREA	DALLAS	DENVER	HOUSTON
How would you rate your small area employment estimates in an overall sense?	In the broad sense, the model works well; allocation is accurate in historical patterns.	Unsatisfactory, we are still working out a lot of bugs in the data and model.	Good, the model and data are reliable. The model is being updated to incorporate economic indicators.	Functional, but work is being done to correct some problems with high residuals.
Do you have a developed relationship by employment type and land use in your model?	Yes, using county business patterns, a 5-industry breakdown is possible. The resulting patterns are projected out to planned uses.	Not enough past to develop a strong relationship.	Yes, the region is broken down into the 1 digit SIC code by small area use.	Yes, data is available to estimate employment by SIC one digit code. Adjustments are made to model as projection periods increase.
How do you check for accuracy in your data and estimates?	Data sets are updated annually and local governments check ABAG estimates for accuracy.	Data sets are updated every two years. Accuracy is assessed by comparing present figures with forecasted figures on the municipal level.	Data set is updated by DRCOG and the State. Accuracy is not checked yet.	Data is updated by state and HGAC; accuracy is checked by very limited employer surveys.
What is the final or smallest area you estimate to?	Census Tract	Census Tract and/or Zip Code	Census Tract	Census Tract and/or Zip Code
QUESTION	LOS ANGELES	MINNEAPOLIS	SAN DIEGO	SEATTLE
How would you rate your small area employment estimates in an overall sense?	Good, the model is accurate in all current surveys.	Done on an individual basis; overall estimates are compiled from community estimates.	Very good, allocation model is acceptable as residuals are low.	Good, historical patterns fit. Sample surveys show strong conformity.
Do you have a developed relationship by employment type and land use in your model?	Yes, regional figures are allocated on the basis of SIC code employment by dominant land use of small area.	No, regional totals are allocated by cities for their metro area.	Yes, a projected land use model projects employment by planned use. Employment projections are based on interacting models of SIC employment.	Yes, employment control totals are allocated from top down based on 1 digit code, factors are adjusted from year to year.
How do you check for accuracy in your data and estimates?	Data is updated by SCAG as it is received from county. Accuracy is checked by municipalities on individual data collections by the cities.	Data is updated every year and model every 5 years. Accuracy is checked by separate metro areas.	Data is updated yearly based on county business patterns. Attraction factors based on employment projections for land use are adjusted by local governments.	The Putman model is used with 6 SIC codes. This derivative model is augmented with interacting runs that attempt to locate addresses that are reporting employees for different locations.
What is the final or smallest area you estimate to?	Census Tract	Census Tract, or special high density districts, mostly in CBD	Census Tract and/or Zip Code	Census Tract and/or Zip Code

FIGURE II-4

CONTROL TOTAL EMPLOYMENT PROJECTION TECHNIQUES BY SELECTED COUNCILS OF GOVERNMENT

QUESTION	BAY AREA (ABAG)	DALLAS (NCTCOG)	DENVER (DRCOG)	HOUSTON (HGAC)
Who produces the employment projection?	ABAG collects all data and does all projections themselves.	The Regional Data Center within NCTCOG does the projection.	DRCOG does the projections themselves.	HGAC does the projections themselves.
How often are the projections done?	Updated every 2 years.	Have committed to a 3-year schedule.	Approximately every 5 years.	Approximately every 3 years.
How are the projections done? What model and/or methodology is used?	Output drives employment which drives population. The RIS ¹ model is used for regional data whereas the CEFS ² model is used for county data. The input-output model deals with 32 sectors. Equations for the model are developed, based on factors such as land use availability, historical trends, decentralizing industries, shifts, etc. The projections are based on historical data. This historical data is refined through the use and evaluation of expert opinions to pick up shifts within the counties.	A demographic task force is used because local input is considered as important as the model forecasting. Regional control totals from the state comptroller forecasts are used. In these totals, employment does not drive population. These totals are allocated across regions using a model in which employment does drive population. The model deals with 5 sectors: manufacturing, retail, commercial, services and government. Construction is completely outside the model. Employment estimates are based on small area employment (# people in building) and tracking of movement of major employers.	Regional level data is used and then allocated to smaller levels, such as county levels. The Shift Share Model, developed by the Center for Economic Forecasting at Regis University, is used. This is a 20-sector model. Essentially, the national numbers are used in a series of regressions to tie Denver-area employment to the national trend. The model is employment-driven.	Controls are developed by region with an 18-sector model. An expert panel of 20 to 30 people is gathered to discuss 'likely' future events. They make an educated guess or preliminary projection to 2020, which is sent out for review. Also, Perryman Growth Rates, National Planning Data, Center for Public Policy Data and trend signals are compared and an average is created. This average, along with the preliminary projection is used to develop control totals. The totals are reviewed by Data Services Committee.

¹Regional Information System.

²County Employment Forecasting System.

FIGURE II-4 (continued)

CONTROL TOTAL EMPLOYMENT PROJECTION TECHNIQUES BY SELECTED COUNCILS OF GOVERNMENT

QUESTION	LOS ANGELES (SCAG)	MINNEAPOLIS (TCAG)	SAN DIEGO (SANDAG)	SEATTLE (PSRC)
Who produces the employment projection?	SCAG works with the Center for Continuing Study of California and UCLA Bureau of Forecasting	TCAG does projection themselves.	SANDAG does projection themselves.	PSRC does projection themselves, but compares numbers with Office of Financial Management
How often are the projections done?	Done in a 3-year cycle (latest 1989)	Approximately every 5 years. Number moves along with long-range planning.	Historically every 3 to 4 years.	Approximately every 2 years.
How are the projections done? What model and/or methodology is used?	Employment drives housing and population. National forecasts from BLS are disaggregated to county level. A forward forecasting method is used. That is, a percent change up or down in employment is constant over time. SCAG does not strictly use historical data. Things specific and important to an area, such as zoning law changes, are considered.	A time series regression approach is taken. National forecasts from BLS and DRI are used in the regression to tie Twin City employment to the national trend. The National Control Total is allocated to 8 sectors as well as 5 rings. These sectors and rings are then allocated to cities. If county data is needed, the data is reaggregated up to the county level. Population forecasting is done separately.	Employment drives population. Migration is determined by employment changes and unemployment forecasts. Cohort components are integrated. A custom developed demographic economic forecasting model is used. Separate economic equations for each employment sector are developed using historical data. The regression takes into account certain factors (national trends, employment, personal income, IO coef.) which are merged into an index. The model has options depending on how the residuals are treated. The model mainly uses 2 digit sectors, but some 3 digit sectors are used for important industries.	Employment drives population. National and regional economic forecasting gives countywide employment numbers. The forecasting model, STEP, is used. (Independent documentation received and verified.)

III. GEOGRAPHIC BOUNDARIES

1.0 INTRODUCTION

The purpose of this technical memorandum is to describe the work performed by Economic Strategies Group (ESG) and GIS Southwest in updating geographic boundaries, as specified under Task 3 of the Socioeconomic Models Enhancement Project. This task contains two distinct work items. The first involves updating Traffic Analysis Zone (TAZ) boundaries, and creating new TAZs to achieve greater consistency with Census geography. The second, requires the development of a book profiling each of MAG's Regional Analysis Zones (RAZs).

The two sections of the memo that follow describe the goals, approach, and results of work on each of these distinct parts of the task. However, the primary products of this task are digitized maps, and printed RAZ profiles not included herein.

2.0 TAZ AND RAZ BOUNDARY CHANGES

The reasons for reviewing TAZ boundaries was essentially two fold. It was the desire of MAG to see if TAZ geography could be more closely related to Census geography, facilitating the use of information from both sources; and to prepare for the year 2000 Census by adding and/or revising TAZ boundaries, especially with respect to existing and future transportation system alignments, development boundaries, etc.

Work of preparing new TAZ boundaries consisted of four tasks:

- 1) Economic Strategies Group reviewed the existing TAZ boundaries as compared to Census Tracts and incorporated area boundaries. The goal of the review was to identify where existing TAZ boundaries would need to change, and new TAZs need to be created, in order to allow TAZs to be equal to, or subsets of, Census Tracts. In the existing system, TAZs boundaries were found to very often span Census Tract boundaries, but sometimes only by a very small amount.

For example, in some places the TAZ boundary would be at the street centerline, while the Census Tract boundary would run along the edge of the street or be one row of houses back from the street. Sometimes these alignments were necessary to follow jurisdictional limits, and sometimes they were not.

It was determined that if a new TAZ were to be created in every case where such an instance occurred, the total number of TAZs would be too large, and many TAZs would not meet the criteria of the traffic forecasting models. As a result, a geographic element called a "TAZLETTE (TAZL)" was created. TAZLs are to be maintained by the socioeconomic system to allow for consistency with Census data, but will not become part of the traffic forecasting system.

The review resulted in recommended TAZ boundary changes drawn onto a series of 88 urban, and 6 rural maps submitted to MAG for review.

- 2) MAG and MAG TPO staff reviewed the changes recommended by ESG. This review focused on two additional factors to be considered in developing TAZ boundaries. The first was the consistency between TAZs and Census Block-groups. It was felt that where it was easy, TAZ boundaries could be changed to be consistent with this second level (in addition to Census Tracts) of Census geography.

Second, was that existing TAZ boundaries should be changed to better align with major streets, and reflect natural and man-made impedances to travel. In some cases this involved adding new TAZs, while in others it was possible to change the boundaries of existing TAZs to achieve consistency.

- 3) Approved changes recommended by ESG, and additional changes recommended/required by MAG staff were transmitted to ESG in two series of maps and documentation as described above. ESG staff reviewed and combined recommended changes into one map "manuscript" to be used by GIS Southwest in creating the new digitized TAZ map. This also included a change in RAZ boundaries requested by the City of Goodyear.
- 4) Based on the manuscript of desired changes, GIS Southwest created a new digitized TAZ map using Arc/Info. Wherever possible, changes to the TAZ system were implemented by selecting arcs from the Census Block geography to form the boundaries of new and revised TAZs.

It should be noted that in the process of incorporating the changes and creations included in the manuscript, GIS Southwest staff encountered a number of areas where very small differences between Census Tract and TAZ boundaries existed, but were too small to be seen on the maps used to develop the manuscript. The vast majority of these involved pieces of land too small to support population or employment. In these cases, the goal of making TAZs and Census Tracts coterminous was used as the over-riding factor in determining the new boundary of the TAZ.

The resulting TAZ boundaries were used to create new RAZ boundaries using the same area contained in existing RAZs, with the exception of the Goodyear area where RAZ boundaries were revised.

3.0 RAZ PROFILES

Regional Analysis Zones (RAZ) have been profiled by Economic Strategies Group (ESG) to serve the Maricopa Association of Governments (MAG) as a concise review of existing and projected population and employment, and planned and proposed development within each of MAG's 141 Regional Analysis Zones. The profiles include a statistical survey of population, employment, and land use data. Information on the major employers and major planned area developments for each RAZ is also included. A short text description is provided as a brief overview of the general characteristics of each RAZ and notable physical, economic, or transportation features. The following is a description of the database tables and data components utilized in the profiles.

List of Database Tables:

- GeogArea: ESG TAZ/RAZ/MPA cross-reference table
- Pop_HU93: MAG population and housing estimates and projections
- LndUse93: MAG land use estimates and projections
- Jails/Institutions: ESG correctional and dormitory facilities
- Nursing Homes: ESG nursing home facilities
- Hotels: ESG hotels and motels
- MHP: ESG mobile homes and travel trailers
- MagEmp: ESG major employers
- Planned Developments: ESG planned area developments

Population. Sources for data included in this section are the 1990 Census and MAG's most recently approved projections for population and housing units for the years 2005 and 2020. Subgroups include household and group quarters population, and transient and seasonal population.

Employment. Sources for data included in this section are the 1990 Census and MAG's most recently approved projections for employment for the years 2005 and 2020. Total employment is stratified into Office, Retail, Industrial, Government, and Other employment.

Land Area. MAG is the source for this land use data, expressed in square miles. Total land area is always given, more detailed information is not available in all cases and is noted as "N/A". Detail includes the amount of undevelopable land, and developed and undeveloped land. Developed and undeveloped is further defined as to residential or employment uses.

Group Quarters Population Generators. Sources for this data are tables compiled by Economic Strategies Group. Data is expressed in number of beds. Dormitories are those located at Arizona State University and Grand Canyon College. Nursing homes include intermediate and skilled care facilities, but not home or hospital-based facilities, as is consistent with U.S. Census definitions. Correctional populations includes county, state, and federal correctional facilities.

Transient Population Generators. Sources for this data are tables compiled by Economic Strategies Group. Data is expressed in units for mobile homes and travel trailers, and rooms for hotels. Mobile homes and travel trailers are those located in parks within Maricopa County. Hotels (including motels) are those located within metropolitan Phoenix and Gila Bend.

Major Employers. Source for this information is the major employer table compiled and updated by Economic Strategies Group. In cases where a RAZ contained more than five employers on the table the top five, by number of employees, are listed.

Planned Area Developments. Source for this information is the planned developments table compiled and updated by Economic Strategies Group. In cases where a RAZ contained more than five developments on the table, the top five, by number of acres, are listed.

IV. COUNTY-LEVEL PROJECTIONS

1.0 INTRODUCTION

This working paper and its associated tables have been prepared to address the need for detailed demographic information for certain socioeconomic variables. Specifically, this task is focused on developing county-level projections of resident group quarters population and non-resident population.

This paper includes a description of data collection and analysis efforts, the methodology by which such data was utilized to create a baseline of information and projections of the various population groups and sub-groups, and the resulting tables including 1990 and each of the forecast years from 1995 to 2040 in five-year intervals.

1.1 DEFINITIONS

Group quarters population is a component of resident population as defined by the U.S. Bureau of the Census. This report estimates and projects the levels for each of these types of group quarter population:

- Military bases
- Jails and prisons
- Colleges and Universities
- Nursing homes
- Other group quarters

Non-resident population groups include persons residing in the county on a temporary basis whose primary place of residence is elsewhere. Non-resident population groups contained in this report include:

Transient Populations

- Hotels and motels (Additionally, the hotel/motel component is further categorized as to leisure, business, group related travel, and other transient populations.)

Seasonal Populations

- Mobile home parks
- Recreational vehicle/travel trailer parks
- Seasonal population residing in dwelling types

2.0 GROUP QUARTERS POPULATION

Total projected Group Quarters Population is presented in Table IV-1. These projections are based on the components of group quarters population projected as follows:

Military Bases. There are currently two military bases in Maricopa County: Luke Air Force Base and Williams Air Force Base. The latter is currently being demobilized, which should be completed prior to 1995. Interviews conducted by Harry Wolfe (MAG Transportation Planning Office) at Luke Air Force Base indicate that there are no plans for down-sizing or expansion of housing; if/when additional staffing takes place the housing is expected to be off-base. There are no known plans for any additional military-driven group quarters expansion in Maricopa County. This is consistent with current national trends.

The base military group quarters population was taken from the 1990 Census. The component for Luke Air Force Base was held constant throughout the projection series. The Williams Air Force Base group quarters was held constant, and used from 1990 to 1993 only.

Jails and Prisons. Incarceration facilities include county, state, and one federal institution. City jails were not included as they are used for very short-term purposes, primarily utilized as holding cells prior to transfer to a county or state facility.

The 1990 baseline for jails and prisons was taken from the 1990 Census. Attempting to accurately project future growth of prison populations is extremely complex as such growth is as much or more a function of public opinion, politics, and funding as it is a reflection of the total population. Interviews were conducted with federal (Patty Garret, Federal Corrections Research), state (Daryl Fischer Arizona DOC Research Unit Supervisor), and county (Chief John Coppock, Sheriff's Office) corrections officials. The information received regarding plans for future growth indicated that using a proportion of the total population would be appropriate. The ratio of .399% of the total population was derived from the 1990 Census.

College & Universities. There are currently two institutions with on-campus living facilities in Maricopa County: Grand Canyon University and Arizona State University. There are no plans to build additional housing at Grand Canyon; there are no plans to build housing at the ASU West campus; and there are no plans to build additional housing at the ASU Main campus, which is building-space constricted. While the ultimate usage of Williams Air Force Base is in doubt, the current re-use concepts indicate that its group quarters housing may be used by an academic facility.

The 1990 baseline population in college dormitories was taken from the Census. The estimates for 1993 were obtained directly from representatives of the two institutions listed above. At Grand Canyon College, the representative was Holly Osmus, and at Arizona State University it was Laura Christianson. They said there are no plans for expanding dormitories at these institutions.

While not currently planned, it seems unlikely that no additional facility of higher education will be needed to serve Maricopa County's growing population and house its students. Therefore, the total number of students projected to be housed in group quarters were based on the 1993 share of County population aged 18 to 22 residing in group quarters (3.0785%), applied to DES projections of population in this age cohort (see Table IV-2).

Nursing Homes. Nursing home institutions as included in this report include facilities for skilled and supervisory care as licensed by the state of Arizona Department of Health Services.

The 1990 baseline for the Table IV-1 Nursing Homes column was taken from the 1990 Census. An interview with nursing home representative Jody Brown at Life Care Center of Scottsdale (part of a company operating nine nursing home centers in the metro-area) indicated that the usual resident in such facilities is at least 65 years of age or older (her estimate was 99%, with an average age of 85). This is consistent with Census information for 1990 showing 8659 persons in nursing homes (from STF 1) and 8242 institutionalized persons in group quarters 65 years and over (from STF 3), or 95.18%.

Therefore, projections of nursing home population, as shown in Table IV-3, were based on the percentage of the population aged 65 and over in nursing homes in 1990 compared to the entire population aged 65 and over. This percentage, 3.26%, was then applied to the Department of Economic Security projections of the population aged 65 and over to yield projections of nursing home group quarter population.

Other and Total Group Quarters. Other group quarters components include mental and juvenile institutions, emergency shelters, persons visible in street locations, and other group quarters as defined by the U.S. Census. The chosen methodology assumes that other group quarters will remain a constant percentage of total population as based on the 1990 Census. This percentage is .45%.

Total group quarter population is simply calculated as the sum of the group quarters components described above.

3.0 NON-RESIDENT POPULATIONS

The Maricopa Association of Governments requires an estimate of non-residential population to facilitate transportation, air and water quality planning. For this reason, peak non-residential population has been estimated in order to plan for increased infrastructure capacity. Non-residential population, for the purposes of this study, consists of transient and seasonal components.

3.1 TRANSIENT POPULATION

For this study, a baseline and projections were first derived from information on average occupancy. Peak occupancy rates were then applied to reflect peak conditions. Accordingly, Table IV-4 is in two parts, the upper area showing average hotel occupancy, and the lower area showing peak hotel occupancy. Each segment consists of two main groups, hotel and motel rooms; and persons staying in those rooms. The information on persons in hotel and motel rooms is further divided into sub-groups: Leisure, Group, Business, and Other Visitors.

To create a baseline of information, an inventory of hotel/motel rooms was first compiled with information provided by Kammrath and Associates, with some revisions based on information from local business and general newspapers. This inventory included information on the year the facility was built which allowed inventories for 1985, 1990, and

1992. These establishments were categorized by class (economy — constructed prior to 1970 or with less than 100 rooms; mid-priced — constructed in 1970 or later and with 100 rooms or more; or luxury) and by region (Northwest, North Central, Downtown, Scottsdale area, Camelback corridor, Airport area, Tempe/ASU area, and East Valley), as defined in Figure IV-1.

From market studies by Deloitte & Touche, average occupancy rates for each class and region were determined and then averaged to create an overall average occupancy rate of 59.17% in 1990. From the same source, the occupancy percentage of each sub-group and persons per room was determined to be:

<u>Sub-Group</u>	<u>Occupancy</u>	<u>Persons/Room</u>
Leisure	29.61%	2.0
Group	21.97%	1.35
Business	44.37%	1.0
Other	4.07%	1.5

The 1990 baseline for occupied rooms was determined by multiplying the actual room inventory by the average occupancy rate (59.17%). The 1990 baseline for the Leisure, Group, Business, and Other components was determined by multiplying the number of occupied rooms by the proportion of occupancy and the number of persons per room for each of the components.

Transient population projections throughout the forecast series were based on projecting people in each of the demand components (Leisure, Group, Business, Other). Projected room occupancy was based on the number of people in each component divided by the number of persons per room.

To determine projected room inventory, discussions with hotel industry consultant John Pappas indicated a gradual trend of increased occupancy rates to reach 70% in 2040. Room inventory was then projected using those increasing levels of projected room occupancy. Forecasts for each demand component were prepared as follows:

Leisure Visitors are from domestic and foreign sources and projections were based on total populations of those sources. Local studies of tourism by Behavior Research Center (Metro Phoenix Visitor Study, draft 1992) and NAU Arizona Hospitality Research & Resource Center (1990-91 Arizona Visitor Profile, 1992) provided information on what states, regions, and nations Maricopa County visitors come from, and what proportion of total visitors they represented in 1990. Table IV-5 shows the results of applying these percentages to the population of those U.S. states and regions as projected by the Bureau of Economic Analysis.

Primary sources of foreign visitors to Maricopa County, 12% of the total visitors, are shown in Table IV-6, with Table IV-7 showing the results of applying the percentage of total visitors from those nations to their projected populations as per United Nations Department of International Economic & Social Affairs projections (World Population Prospects 1990, medium variant used).

Group Visitors were determined to be from domestic sources with growth of the component viewed as a function of the economy in other states. Lacking specific information on sources of group visitors, it was reasoned that similar motivations regarding destination would apply to group as well as to leisure visitors from the domestic sources. Therefore, only the domestic component of the data was used to derive a percentage of visitors from states and regions. Projections were based upon employment levels in those states as projected by the Bureau of Economic Analysis, multiplied by the percentage of the total visitors to Maricopa County from the 1990 baseline with the results shown in Table IV-8. This also differs from the Leisure component in that population was used to drive the projections for that component.

Business Visitors were determined to be from domestic sources with growth of the component viewed as a function of the local economy. As shown in Table IV-9, a baseline of the 1990 employment level in Maricopa County and projections to 2040 were determined from employment data from the Maricopa Association of Governments (MAG). The total of business visitors in Table IV-9 and Table IV-4 is a constant percentage of Maricopa County employment in the forecast years. This percentage is 9.77%.

Other Visitors were viewed as a proportion of visitors from the three primary components: Leisure, Group, and Business. This proportion, 4.93%, is an average drawn from 1985 and 1990 information. Therefore, projections for other visitors, or other transient population, was derived from summing the Leisure, Group, and Business components and multiplying by 4.93%.

Peak Occupancy Projections. Once average occupancy rates and populations were established it was possible to determine peak transient populations. Information was obtained from the Phoenix & Valley of the Sun Convention & Visitors Bureau showing peak occupancy levels of:

<u>Year</u>	<u>Peak</u>	<u>Average</u>	<u>Ratio</u>
1990	87.7%	62.8%	1.3965
1991	85.0%	60.3%	1.4026
1992	80.2%	62.6%	<u>1.2812</u>
Average:			1.3624

Note that differences between the Deloitte & Touche and the Phoenix & Valley of the Sun Convention & Visitors Bureau in 1990 average occupancy are due to differences in methodology and inventory included. The ratio of peak to average occupancy rates is nonetheless a valid factor in predicting peak population.

The average peak occupancy levels were divided by the average occupancy levels with the results averaged, resulting in a factor of 1.3624. Peak occupancy/population was derived by multiplying the average occupancy/population by that factor throughout the projection series (lower half of Table IV-4).

3.2 Seasonal Population

The other main component of non-residential population is seasonal population. Table IV-10 is a compilation of seasonal population residing in mobile homes, recreational vehicles/travel trailers, and within resident housing. These component groups are addressed separately.

Seasonal Population Residing in Mobile Homes. The baseline information for this component was taken from the 1992 edition of the annual Winter Resident Study of seasonal visitors by Arizona State University, Center for Business Research. The Table IV-11 inventory was adjusted to subtract Pinal County mobile home parks from the ASU study. Peak occupancy levels according to the study were 87%, with 45% being occupied by seasonal (winter) visitors. Seasonal population was determined by multiplying that seasonal occupancy by 2.0 as indicated by this Winter Resident Study from Arizona State University.

Seasonal population in mobile homes seems to be a function of age and place of primary residence. It was determined through the 1993 Winter Resident Survey prepared by the Market Research Department of the Arizona Republic/Phoenix Gazette and conducted by Arizona State University that the typical seasonal visitor staying in a mobile home is 65 years of age or greater; the place of primary residence was taken from the same survey. A majority of those surveyed were multi-year visitors so major geographical shifts were deemed unlikely.

While the survey showed 17% of seasonal visitors were from Canada, the specific province was not indicated. For these projections, it was determined to consider the four southwestern Canadian provinces (Manitoba, Saskatchewan, Alberta, and British Columbia) as the source of visitors. This area is roughly consistent geographically (taking into account distance and population centers) with the domestic sources of visitors, that is, primarily near the Mid-Western and Western regions of the U.S.

The results of applying the baseline percentage of seasonal visitors in mobile homes by place of primary residence to the population aged 65 and greater in those states and provinces is shown in Table IV-12. Those projections of seasonal population were transferred to Table IV-11; the inventory, occupancy, and seasonal occupancy columns were then derived using the 1990 baseline census ratios of 2.0 persons per unit, 87% occupancy of which 45% was seasonal.

Seasonal Population Residing in Recreational Vehicles. The baseline information for this component was taken from the 1992 edition of the annual Winter Resident Study of seasonal visitors by Arizona State University, Center for Business Research. The Table IV-13 inventory was adjusted to subtract Pinal County RV parks from the ASU study. Peak occupancy levels according to the study were 90%, with 82% being occupied by seasonal (winter) visitors. Seasonal population in RV's was determined by multiplying that seasonal occupancy by 2.0 persons per unit as indicated by the Arizona State University study.

Seasonal population in RV's was viewed as a function of age and place of primary residence as with Mobile Homes. It was determined through the 1993 Winter Resident Survey prepared by the Market Research Department of the Arizona Republic/Phoenix Gazette and conducted by Arizona State University that the typical seasonal visitor staying in an RV is 65 years of age or older; the place of primary residence was taken from the same survey. The same method used to project demand by residents of Canada was used for Mobile Homes, described above.

The results of applying the baseline percentage of seasonal visitors in RV's by place of primary residence to the population aged 65 and greater in those states and provinces is shown in Table IV-14. Those projections of seasonal population were transferred to Table IV-13; the inventory, occupancy, and seasonal occupancy columns were then derived using the 1990 baseline ratios of 2.0 persons per unit, 90% occupancy of which 82% was seasonal.

Seasonal Population Quartered in Other Housing. The baseline for Table IV-15 was derived from 1990 Census data. The 1990 Census contains information on the vacancy status of housing units. The units which could be considered to house seasonal population are those vacant units held for seasonal, migrant or other uses, as defined by the Census. For 1990, this number was 56,220, or 5.905% of the 952,041 total housing units in Maricopa County. Seasonal mobile home units, accounted for earlier in this study, were subtracted from total seasonal housing to yield other seasonal housing units.

Projections in Table IV-15 were derived by using MAG projections of total housing units multiplied by the same ratio (5.905%) of seasonal to total housing units to project seasonal housing units. Seasonal mobile home units were subtracted to yield other seasonal housing. The projection for the seasonal resident population in other housing was derived by multiplying the seasonal units by 2.0 persons per unit as indicated by Arizona State University studies on seasonal visitors.

4.0 COUNTY-LEVEL DEMOGRAPHIC CHARACTERISTICS

The final section of this white paper presents selected demographic characteristics to be determined under this task of the Socioeconomic Models Enhancement Project. In general, these characteristics are quantitative socioeconomic and demographic factors required in developing small-area projections of population and employment.

Specifically, the relationships quantified include:

- Income characteristics
 - Workers per household by income quintile
 - Workers per household by income quintile and economic sector
 - Population per household by income quintile
 - Retirement population by income category
- Unemployment rates by sector
- Vacancy status by unit type

Measurements for all of these characteristics were derived from the 1990 Census Public Use Microdata Sample (PUMS) for Maricopa County, Arizona. Household and person information was extracted and combined as necessary to enable the desired cross-tabulations to be performed. The results are as follows.

4.1 WORKERS AND PERSONS PER HOUSEHOLD

Table IV-16 shows the population and number of households in Maricopa County for MAG income quintiles based on the PUMS sample. The household income breakpoint for the quintile were \$15,000, \$25,000, \$35,000 and \$50,000. The income quintiles in the sample contain between 6,158 and 9,526 households each.

The lowest quintile, households with \$15,000 or less in annual income, had an average size of 2.06 persons, with only 0.60 workers. In the second quintile the population per household increases to 2.31, while workers per household increases to 0.99. Both household size and number of workers increase with income, although in the upper quintiles the number of workers increases faster than the size of the households. In the highest quintile, households with annual incomes of more than \$50,000, the household size is 3.11 persons, 1.77 of whom are workers.

The overall averages calculated from this sample, 2.64 persons per household and 1.26 workers per household, are both very consistent with the County levels. The 1990 Census reported an average household size of 2.59, and the imputed number of workers per household was 1.28.

A similar measurement, workers by household income quintile AND economic sector is shown in Table IV-17. These figures reflect the distribution of workers by household income category based on the industry of the employed person.

The results show distinctive differences in the household incomes of workers in different industries. As expected, the agriculture industry has the largest share of workers in households in the lowest income range. Somewhat surprisingly, the Utility Industry has the largest share of its workers in the highest income category.

The exact cause of the variation among industries is somewhat more difficult to interpret. It seems that household income level of persons could be impacted by a great number of variables including, but not limited to:

- Wage levels in the industry
- Demographics of persons employed in the industry
- The prevalence of unions, etc. in some industries

Overall, it seems that the income categories are too low, grouping too many workers in the highest income category.

4.2 RETIREMENT POPULATION BY INCOME CATEGORY

Using the income categories described above, Table IV-18 demonstrates the relatively lower incomes of the retired population. In this analysis, households with heads over age 65, and those with a majority of people over age 65, were determined to be "retired" households.

The sample data shows that about 43 percent of the retired households have incomes placing them in the bottom quintile of all households. However, since the persons per household

figure in the category is only 1.43, the total share of retired population in this category is 36.3 percent. This compares with 2.06 persons per households, representing 15.7 percent of the population in the bottom quintile for the general population.

In each income category the household size of the retired population is much smaller than in the general population, rising to only 1.99 in the uppermost income categories. The data also clearly demonstrates how incomes are affected by the loss of a spouse, since nearly half of the households in the lowest category appear to contain only one person.

To determine projections of retirement population by income quintile, population by age projections for age 65 and over from the Arizona Department of Economic Security are used. The 1990 share of population in each income category is applied to the projected population over age 65 to yield projected retired population by income category.

The resulting projections, shown in Table IV-19, are in constant 1990 dollars and do not reflect real growth in income over the period, if any. Although the thresholds for income categories will change significantly in terms of current dollars, there is no evidence to suggest that the share of population in each quintile will change significantly.

4.3 UNEMPLOYMENT RATES BY SECTOR

Table IV-20 shows unemployment rates by economic sector as derived from the Census PUMS sample. This data represents the conditions in early 1990, when the total unemployment rate was around 5.5 percent. It has, of course, increased significantly since then. The industry detail shown was selected to generally correspond with that reported by the Arizona Department of Economic Security for Maricopa County.

The rates show significant differences in employment characteristics across the sectors. Unemployment rates were highest in mining (16.7 percent), and lowest for utilities (2.2 percent). However, it must be noted that the rate for mining may be distorted due to the small number of observations included in the PUMS sample.

Unemployment rates in other sectors seem very reasonable. Agriculture and construction were high at around 10 percent, while government and professional services were quite low at between 2.7 and 2.9 percent. Others generally fell in the range of 4 to 7 percent, which again seems reasonable.

Although it is expected the some changes will occur in these unemployment rates over time, we can find no predictions of exactly how these changes will occur. The number of persons in any given industry can change relatively quickly, as industries expand or contract -- the result of having a mobile work force. Thus, the relationship of unemployment rates across industries is more a function of the characteristics of the industry than of economic condition. While the overall unemployment rate may vary significantly over time, there is no prospective information for changes in the relationship across industries.

4.4 VACANCY STATUS BY UNIT TYPE

This piece of information is provided as an informational item in the further exploration of Census vacancy rates. Table IV-21 shows vacancy status statistics by unit type for Maricopa County, as well as 16 Public-Use Microdata Areas (PUMAs), all based on the 5 percent sample data from PUMS.

This information shows the distinction between units that are vacant from a real estate perspective (for rent, for sale, sold or rented but not occupied), versus those which are typically vacant but are held for seasonal, recreational and other uses.

Based on total housing units, the sample data in Table IV-21 is fairly consistent with the 100-percent count number available from the Census (adjusted vacancy of 11.13% for PUMS versus 9.85%). The information added through using PUMS data is the detail for adjusted occupancy rates by type of unit. The data for each PUMA is supplied so that this information could be used to estimate seasonal housing units on a sub-county level.

V. EMPLOYMENT DATABASE

1.0 INTRODUCTION

The Maricopa Association of Governments (MAG) requires information on areas of traffic generation to assist in their transportation planning and trip reduction efforts. This working paper and its associated materials have been prepared to identify and inventory major employers in Maricopa County, and will include a description of the data collection efforts involved and the resulting database file.

1.1 DEFINITIONS

Major employers were defined as those employers, in the public or private sector, with 50 or more employees at a site. The information is site specific; in cases where an employer had multiple sites, they are reported separately. Restaurant and convenience store franchises were not included due to the lack of site-specific information.

While the focus of this data collection effort was employment sites with 50 or more employees, there were sites included with fewer than 50 employees. In some cases, verification of secondary data showed fewer than 50 employees. In other cases, certain sites within a group of related sites contained fewer than 50 employees. It was decided in such cases to retain the information on those sites, considering that in the future additional employment may occur at those sites.

2.0 EMPLOYMENT DATA COLLECTION

Initial data collection efforts involved acquiring database files from MAG (six files with 1,826 records) and Claritas National Planning Data Company (one file with 2,891 records).

These database files were combined to form a single database of 4,717 employer site records. Multiple sorts on company name and address fields were performed to identify and mark duplicate records for deletion. Actual deletions were not executed until a determination was made regarding which records had the more accurate and/or recent information.

Information obtained from Claritas provided an estimated range of the number of employees at each company listed but no specific number. For the approximately 1400 companies where other verification sources were unavailable, telephone contacts were made to obtain specific employment information and to verify address. These calls were made over a three week period in December 1992 and January 1993.

For chain-store operations, such as grocery stores, site information was obtained through U.S. West telephone directories. Employment information for those companies was obtained through a representative sampling of individual sites from the companies' various

metropolitan Phoenix locations, with the resulting average applied to the remaining company facilities.

Other sources utilized to verify information or to add additional sites include:

- 1991 Arizona Industrial Directory, for information about employment in manufacturing firms.
- Arizona Department of Education, for information about employment in public schools.
- Arizona Department of Commerce, for information about employment by state agencies.
- The Business Journal, Book of Lists.

Throughout the data collection and verification process, local newspapers and business periodicals were referred to regarding facility openings, closings, or changes in employment.

A draft of the information collected was delivered to MAG, who in turn provided member agencies with the site employment information pertaining to their cities. These MAG member agencies reviewed the information and compared it to their own sources. Recommendations for changes, additions, and deletions were received from the cities of Phoenix, Glendale, Chandler, Peoria, Goodyear, and Buckeye. These revisions were then incorporated into the database of information.

3.0 EMPLOYMENT DATABASE RESULTS

The data collection effort outlined above resulted in a database of 3,018 employment sites with a total of 488,431 employees. This employment count is shown on Table V-1, grouped by MPA (Metropolitan Planning Area). This is 48.51 percent of the total civilian employment or 48.95 percent of the total wage and salary employment for Maricopa County as of June, 1993 as per the Arizona Department of Economic Security Research Administration report Maricopa Labor Force and Employment in 1993.

Of the total employees contained in this database of major employers, 92.57% were in six MPA's:

<u>MPA</u>	<u>Percent of Total Employees</u>
Phoenix	55.82
Tempe	9.93
Mesa	8.70
Scottsdale	8.04
Glendale	5.97
Chandler	<u>4.11</u>
	92.57

Figure V-1 shows the names of fields contained in the employment database and a description of the information contained in the fields. In addition to fields for company name and address, and number of employees, this database contains fields to identify the original source of the record information, the company's Standard Industrial Classification, and seven fields to store locational information for various geographic regions. Figure V-2 shows descriptions of the various codes used in certain fields of the database.

4.0 EMPLOYMENT/LAND USE MATRICES

This working paper and its associated materials have been prepared to measure the propensity of industries to utilize certain land use types. The research analysis involved in the performance of this study has been conducted at a detailed scale and then aggregated into a more concisely defined final matrix.

This report will include a description of the data sources utilized in the development of an information base, the methodology used to develop aggregated matrices, and the resulting employment-to-land use correlation matrix.

4.1 DATA SOURCES

Land use types utilized for this study were obtained from the Maricopa Association of Governments, General Plan Land Use Codes, MPA "MAGHIGH." The MAG land use codes were aggregated into nine general categories as follows:

- Hotel = Hotel/Motel
Resort
- Retail = Neighborhood Retail
Community Retail
Regional Retail
Strip Retail
General Commercial
- Office = Small Office
Large Office
Medical Office
- Industrial = Industrial/Business Park
Manufacturing
Warehouse
- Hospital = Hospitals
- Utilities = Public Utilities
- School = Schools
- Government = Government/Municipal

Green belts
Mixed use

A tenth code, "None," was added to compensate for those industries or occupations where a specific land assignment was not feasible. This situation is most common in occupations such as transportation and the construction trades, where employment is job or task driven rather than land use based.

Information on occupation types and industry classifications was obtained from the U.S. Bureau of Labor Statistics (National OES Matrices for 1990-2005). This data file lists 620 occupations in 260 industries at detailed and summary levels.

4.2 DATA ANALYSIS

The initial step of the analysis effort consisted of examining each of the occupational categories listed in the Bureau of Labor Statistics matrices and determining in which of the ten land use types such an occupation could reasonably be expected to be present. In some cases, it was determined that a person in a given occupation might be found in more than one of the land use categories. For these cases, scores on a scale of 1 to 5 were assigned to each land use category, modeling the propensity of the occupation to exist in one land use category more, or less, than another.

The list of industries from the Bureau of Labor Statistics matrices was aggregated, using both summary and detailed data, to match, as closely as possible, the industry classifications used by the Arizona Department of Economic Security for compiling labor force and employment statistics. The use of both summary and detailed data ensured that all industry classifications were represented.

Table V-2 shows the results, in number of workers by industry and land use. These numbers were obtained by multiplying the number of workers of each detailed occupation type and aggregated industry classification by the percentage assigned to each land use category.

The results of Table V-2 were converted into percentages in Table V-3 by dividing the number of employees per land use by the total in that industry classification.

It was understood that while certain occupation types could be present in multiple, or all, land use types, they would not necessarily be represented equally in each. Given the size of the data set used to derive the occupation/industry by land use matrix, and the fact that some U.S. industries would have minimal or no presence in Maricopa County, such a matrix would be skewed to some extent toward a national mix of industries and their land use patterns.

In order to compensate for such over- or under-representation, and to make the resulting matrix more localized in scope, the Table V-3 industries were examined and compared to their land use types with attention to local development practices and uses. When a determination was made that an industry's presence in a particular land use was minimal, those land use percentages were changed to 0.00 and reallocated proportionally to the remaining land uses. The results of this analysis and the resulting reallocation is shown in Table V-4.

TABLE V-2
U.S. Employment by Industry and Land Use
Number of Workers 1990

Industry	Hotel	Retail	Office	Industrial	Hospital	Utilities	School	Gov't	Other	None

VI. PARCEL DATABASE

1.0 INTRODUCTION

The purpose of this technical memorandum is to describe the work performed by Economic Strategies Group and GIS Southwest in updating MAG Parcel Database, as specified under Task 6 of the Socioeconomic Models Enhancement Project. This includes the data collected, methodology used, and products created. A "Data Dictionary" of the update database is provided in Appendix A. This provides detail as to the contents of the Database, and the definition of its fields.

2.0 METHODOLOGY

The requirements of the Parcel Database update consisted of two primary work items:

- Using MAG's existing Parcel Database as a beginning point, update as much of the parcel information as possible, and add or delete parcels as necessary; and,
- Geocode (determine an X and Y coordinate for), new parcels added to the Parcel Database.

The scope of the second work item was subsequently expanded to include the geocoding of all parcels, not just new ones. This change was necessary since the X and Y coordinates on the existing MAG Parcel Database were based on different address files and coordinate systems.

2.1 DATA UPDATE

The updated Parcel Database is based on data extracted from MetroScan, a CD-Rom based information product created by Transamerica Information Management Systems. MetroScan combines data from the County Assessor's and County Recorder's files. It merges selected data from all sources into a uniform record for each parcel and building in the County.

The approach was to use MetroScan data to update the existing MAG Parcel Database. The existing database consisted of 846,631 parcel-based records, contained in five files of about 170,000 records each. The division of the database into component files greatly facilitates the processing of information due to the large number of records involved.

Selected data were extract from MetroScan into five datafiles, each for the purpose of updating one of the component files of the original database based on the range of parcel numbers. A computer program was written to merge the original Parcel Database, with the

update records extracted from MetroScan. This program updated selected fields in records for existing parcels, added records for new parcels, and deleted existing records for parcels found without a corresponding update parcel.

This program dealt with the data and address portions of the Parcel Database as separate components, as per the format of the original database. This file organization make some sense since only about 50 to 60 percent of parcels have site addresses. However, since file sizes are not of as much concern as they were when the original database was created, a second program was written to merge the data and address components into a single record for simplicity. This second computer program also re-assigns MAG Land Use (MAGLU) codes as necessary.

Selected fields (parcel number, old "X" and "Y" coordinate, address, etc.), were extracted from these five merged data files for use by GIS Southwest for geocoding. Following geocoding, the resulting "X" and "Y" coordinates, along with the 1990 TAZ, were appended to the data files.

2.2 GEOCODING

Parcels in the database were geocoded using two methods. First, if a site address was provided for a parcel, Arc/Info was used to try and match the address with a specific, geographically coded, street link in Maricopa County. The geographically encoded street system MAGNET was obtained through MAG and converted for use in Arc/Info (Geographic Information System) by GIS Southwest. Note that all parcel geocoded by address matching have "AD" in their "XYFlag" field.

The second method was to use the "X" and "Y" centroids of the Assessor's book-maps for each remaining parcel within that book-map area. This method worked quite well since, in general, book-maps are smaller than Traffic Analysis Zones (TAZs), and the primary goal was to accurately assign parcels to TAZs. There are over 6,000 book-maps in Maricopa County as compared with about 1,300 TAZs. Book-maps are the second level of geography used by the County Assessor to track the location of specific parcels. Each of Maricopa County's approximately 875,000 parcels are located in one of over 6,000 book-maps. All parcels geocoded using book-map centroids have "BM" in their "XYFlag" field.

3.0 PRODUCTS

This task resulted in the creation of two key products. First, was the updated Parcel Database. Figure VI-1 shows the record description for the updated Parcel Database. As noted in the introduction to this memorandum, the Data Dictionary in Appendix A describes the contents of each field on the database. The updated Parcel Database contains a total of 874,298 records, divided into five data files by parcel number range. The range of parcel numbers contained in each of the five parts are shown in Figure VI-2.

Second, was the geographically encoded book-map map created to get book-map centroids for geocoding parcels without addresses. This map, and its more than 6,000 unique book-map regions offer great potential for new uses of parcel-based data. Preparing the book-map map proved to be a much more difficult and costly task than was originally estimated, since good reference maps could not be obtained. Comprehensive maps depicting all Maps within each of the Assessor's Books do not exist. In fact, it was sometimes necessary to access around a dozen maps to see the boundaries of the Maps within a single Book.

5	301-67-402	699-08-906	151,922
Total			874,298

The book-map map provided by MAG as the starting point for the task was a partially complete effort implemented in 1989. It contained only about two-thirds of all book-maps, and a significant number of mis-codings. However, the real problem in creating the new map was that good reference maps could not be obtained. Comprehensive maps depicting all Maps within each of the Assessor's Books do not exist. In fact, it is sometimes necessary to access around a dozen maps to see the boundaries of the Maps within a single Book.

VII. REGIONAL ANALYSIS ZONE: SPECIAL POPULATION PROJECTIONS

1.0 INTRODUCTION

This working paper and its associated databases and tables have been prepared to explore alternative methods for estimating and projecting special population groups at the Regional Analysis Zone level of geography. This paper describes data collection and analysis efforts, and presents methodologies which could be used to create estimates and projections of the various special population groups and sub-groups. These include estimates for 1990, and projections for the forecast years of 1995 through 2040 in five-year intervals for each special population group.

Special populations are divided into two parts, resident group quarter populations and non-resident seasonal and transient populations. Each of these population groups are then further subdivided into specific types of contributors to each special population group.

Group quarters population is that portion of the resident population that resides in non-household living quarters. This includes population in nursing homes, school dormitories, military bases, jails and other institutions such as rehabilitation centers or psychiatric care facilities.

Seasonal and transient population is the non-resident population that resides temporarily within an area at certain times of the year. For the purposes of this analysis, seasonal population is that portion that resides within an area for more than two weeks. This includes people staying within private homes or apartments, mobile homes or recreational vehicles for more than two weeks. Transient population is that portion that resides within an area for less than two weeks and who typically reside in a hotel, motel, or resort.

1.1 PAPER ORGANIZATION

The balance of this working paper is divided into four sections. Section 2.0 reviews the work performed by ESG to inventory existing generators of special populations. These include group quarters housing units, mobile home and recreational vehicle parks, and hotels, motels and resorts. Also included in this section is an inventory of existing retirement-oriented developments in Maricopa County.

Section 3.0 transmits the results of our effort to identify specific future generators of special populations. This includes information obtained through our interviews with city and town planning departments, as well as information obtained through creation of the planned and proposed development database.

Section 4.0 presents the methodology developed by ESG to perform sub-county projections of special populations. In general, these approaches attempt to use the same sub-groups employed in the development of the County-level special population projection methodology. However, in some cases it was found that projecting sub-groups was too difficult.

Finally, Section 5.0 illustrates the projection methodology by presenting RAZ-level projections of special populations prepared by ESG. **These projections are only provided to illustrate the recommended projection methodology, and should not be used in any analysis for any reason.**

2.0 SPECIAL POPULATION GENERATOR INVENTORY

As discussed in the introduction to this paper, special populations consist of both group quarters population, and non-resident transient and seasonal populations. This section describes our approach to developing an inventory of existing generators, our results, and a comparison with estimates currently used by MAG. Figures VII-1 through VII-6 show the contents of the databases prepared to implement the inventory of special population generators.

2.1 GROUP QUARTERS

Overall, the group quarters population estimates prepared by ESG, based on its inventory of group quarter units for 1990, were only 1,413 persons greater than the MAG/Census figures. Larger discrepancies between Census and ESG estimates exist within some of the components of group quarters population, as described below. Most of the differences can be explained through the inherent difficulty of identifying and counting group quarters populations.

Nursing Homes. A listing of currently operating nursing homes in Maricopa County was compiled from the employment database (Claritas NPDC), MAG and Trip Reduction databases, and from information supplied by the Arizona Department of Health Services. In all, over 400 nursing homes were identified with a total of over 22,000 beds. Since not all beds in all facilities are used for permanent residents, it was necessary to determine the portion which are, and to determine occupancy rates for them.

For skilled care nursing homes, occupancy information was available from the Arizona Department of Health Services. However, for supervisory care homes it was necessary to interview a sample of them, and estimate the population in all homes. ESG also identified the number of beds in hospitals which are also occupied by persons on a permanent basis.

The results of the analysis led to a 1990 estimate of 10,213 group quarters residents, as compared with the 8,659 reported by the Census. The difference of 1,554 people could be caused if the supervisory care homes, where the population was estimated, have lower occupancy rates than the skilled care homes. Or, it could be that ESGs simply identified more of the group quarters generators than did the Census.

School Dormitories. School dormitory population estimates were derived through direct interviews with the school involved. Maricopa County schools identified with residential housing included ASU, Grand Canyon University, and the Judson (Prep/Boarding) School. Our interviews with representative at these institutions yielded a 1990 estimate of 5,752 persons, 496 persons more than the Census estimate.

The most important finding of the research performed by ESG in that area was that the dormitory occupancy rates at ASU (by far the majority of persons in this component), have fallen significantly since the 1990 Census. The decline is due in part to a slight decline in enrollment, but is more likely a function of the downturn in the economy in the early nineties, and the subsequent greater availability and affordability of off-campus multifamily housing. Based on renewed economic growth in Maricopa County, we are projecting dormitory occupancy rates to increase steadily over the next several years.

Military Bases. Since military bases are identified by the Census, ESG used those figures for its 1990 estimate of population. Military group quarters population projections are based on the 1,002 residents at Luke AFB. Interviews with officials at Luke AFB indicate that no new on-based housing is planned.

Jails and Other Institutions. ESG's inventory included 15 institutions with a total population of 8,849 persons. This is 377 more persons than were reported by the Census Bureau. The difference might well be caused by simple fluctuations in the inmate population as we were unable to get data from all facilities that exactly coincided with the date of the census, which itself is only nominal.

Other Group Quarters Population. This component is calculated as a percentage of the other group quarters population components, and therefore did not include an inventory component. ESG RAZ estimates and projections, provided for illustrative purposes, are based on this same percentage approach. As a result they tend to vary significantly from the MAG estimates since these are based on Census data at the Block-level aggregated to TAZs and RAZs.

2.2 SEASONAL POPULATION

Estimates of seasonal population were based on our inventory of Mobile Home and Recreational Vehicle (RV) parks, as well as an estimate of the number of people occupying other types of housing units on a temporary basis. As a result of including all of these sources, the seasonal population estimate (164,965 in 1990) is significantly greater than previous MAG estimates. Research performed by A.S.U. indicates a Mobile Home and RV seasonal population of about 90,000 people in 1990. This combined with persons occupying other types of units seems to support the new estimates.

RV and Mobile Home Parks. The inventory of mobile home and RV parks compiled by ESG included more than 600 parks. The number of mobile home and RV spaces were determined for each park based primarily on survey data from Kammrath & Associates. The share of spaces occupied by seasonal visitors was determined from the A.S.U. Winter Visitors survey. Survey results by zip code, not published with the survey results, were provided to ESG to make the estimates more accurate.

The resulting number of spaces/units occupied by seasonal visitors was then multiplied by 2.0 to compute seasonal population from these generators. The figure of 2.0 was developed by A.S.U. in the process of conducting its annual Winter Visitors survey. While it seems likely that the actual number of persons per unit is slightly less than 2.0, no information was available on which to base a better estimate. New survey research would be required to develop a more accurate persons per unit rate.

The research resulted in a peak estimate of 43,636 mobile home, and 52,525 RV seasonal visitors in 1990. The total for these two generators, 96,161 is close to the 90,000 person estimate included in the survey results published by A.S.U.

Other Seasonal Housing. Estimates of seasonal population in other types of housing units were made at the County level by analyzing the number of units reportedly held for seasonal, migrant, or other uses by the Census Bureau. Accordingly, the RAZ estimates included herein are based on similar vacancy status information. The total number of units held for seasonal, migrant or other uses by RAZ was multiplied by 2.0 person per unit to estimate seasonal population in other housing by RAZ.

However, seasonal populations residing in other housing types are also affected by retirement communities, and were therefore inventoried by ESG. This information is especially useful in preparing projections of seasonal population in other housing. Retirement communities are defined as those planned area developments specifically designed for an older population, and which often have restrictions on the minimum age of their residents. For the purpose of this paper, only retirement communities with distinct identities as subdivisions or "new towns," and with populations greater than 1,000 people have been included.

Information on retirement communities was compiled from a 1992 study by Charlotte Welch (Retirement Communities in Maricopa County), the Maricopa County Department of Planning and Development (Large Scale Developments, 1992) and 1993 data on planned area developments prepared by Canyon Research. This information was also enhanced and/or supplemented by site and development plans.

Currently there are twelve of these large-scale retirement communities within the county. The 1990 Census indicated that there were over 230,000 residents age 65 or older in Maricopa County. Of these, almost 92,000 lived in these retirement communities. The twelve communities contain over 25,000 acres of land and have almost 59,000 residential units.

Of the twelve retirement communities listed on Table VII-1, three (Sun City, Sun City West and Sun Lakes) are significant enough to be considered census designated places (CDP) by the U.S. Bureau of the Census. Youngtown is incorporated as a town. Although the larger communities do contain significant amounts of non-residential building space, the predominant land uses are residential and recreational. Every retirement community included on Table VII-1, with the exception of Youngtown, has at least one golf course, and half of those listed contain more than one.

2.3 *TRANSIENT POPULATION*

Hotels, Motels and Resorts. Based primarily on a database purchased from Kammrath & Associates, ESG compiled a database of 337 hotels, motels, and resorts in Maricopa County. Based on data for sub-markets in Maricopa County produced by Deloitte & Touche, the rooms included in the inventory were converted to estimates of transient population. Room occupancy was subdivided into demand components including leisure, group, business and other travelers. Each group was converted to persons using persons/room factors also developed by Deloitte & Touche.

These population estimates were then converted from average occupancy rates to peak occupancy rates using data from the Phoenix and Valley of the Sun Convention & Visitor Bureau. The resulting estimated peak transient population of 40,792 (1990) was somewhat less than estimates prepared previously by MAG. These discrepancies could be due to a differences in the occupancy rates, persons per room or base inventory. The new inventory and population estimates will be used as the baseline for the new projections.

3.0 FUTURE SPECIAL POPULATION GENERATORS

This section summarizes information gathered by Economic Strategies Group through interviews with each jurisdiction in Maricopa County for the purpose of projecting special populations. These interviews sought information regarding any approved, proposed or future plans for the development of facilities for the purpose of housing special populations.

Representatives of the planning departments from the cities and towns were interviewed as well as other key informants from various government agencies associated with institutions generating and/or housing special populations.

For this section of the white paper we will only be concerned with actual planned or proposed development or expansion of nursing homes, dormitories, jails and other institutions as well as mobile home and RV parks, hotels, motels and resorts. Although all the cities within Maricopa County were interviewed, most either had no plans for such development or expansion or were uncertain as to the details. Therefore, little of this information was available for use in preparing the new RAZ level forecasts of special populations.

3.1 GROUP QUARTERS POPULATION

Nursing Homes. In the city of Cave Creek there is some discussion of the development of retirement homes together with some form of medical aid or assistance. Approximately 18 to 20 apartments are proposed and may be completed by 1998. The location would be within the downtown core area, TAZ 5. Model Input: RAZ 207, 20 Units.

In the city of Chandler there is a proposal for development of 400 units. These would be limited care and independent living accommodations, similar to the Friendship Village development located in Tempe. They would be located on the northwest corner of Arizona Avenue and Chandler Blvd, TAZ 1172. Completion of the development is expected in the 1995-2000 time period. Model Input: RAZ 316, 400 Units.

In the town of Fountain Hills there is discussion of development of a rural hospital setting with 24 hour nursing care, housekeeping and residential units as required. It will be located in the downtown area, TAZ 265 or 235. Development is at least 5-10 years away.

There is interest in the city of Gilbert for long term residential care facilities for actively independent adults but there have been no proposals. Model Input: None.

In the town of Surprise there is a proposed expansion of the medical offices and facilities located at Baptist Village, 12215 W. Bell Rd., TAZ 178. Model Input: RAZ 234, 100 Units.

School Dormitories. Although several of the cities within Maricopa County expect expansion of their community colleges, community colleges within Maricopa County do not typically have dormitories located on their campuses. The student demand for housing is usually left to off campus housing. The exception to this is in the City of Avondale where there is an interest in future development of an off campus dormitory just south of the city boundary with Litchfield Park. This would be within an adjacent high density district on Dysart Road, and would meet the housing demand for the planned expansion of Estrella Mountain Community College to 15,000 students by 2005.

In the City of Mesa there is a great deal of speculation regarding the reuse of Williams Air Force Base. Williams AFB is located at Williams Field Rd. and Power, TAZ 1204. Included in this is the possibility of an A.S.U. East Campus. Future development of the site depends on its reuse. If the site is reused as a campus the barracks and single family housing units will be reused as student housing on an as needed basis. Also, Rio Salado Community College at Bush and McKellips, TAZ 662, is likely to expand on their 60 acre site within the next 5-10 years although, like all other Maricopa Community colleges, no student housing is planned.

Assumptions used in the model as per the student population of each of the three sites discussed above is summarized in a later discussion, and in Table VII-8.

The only other school with a residential component is the Judson School in the Town of Paradise Valley. The school is located at Indian Bend Road and Mockingbird Lane, TAZ 421, on a 50 acre site. It is a well established school and new dormitories are proposed in its expansion. The expansion program is gradual and is expected to continue over the next 5-15 years. However, since no firm number of units, or construction schedule exists, no assumptions regarding this expansion were included in this version of the projections.

Jails and Other Institutions. It should be noted at the beginning of this section that in Maricopa County, city jail facilities only detain people for 24 hours and then they must be transferred to a County facility. Also many of the smaller communities contract their police services from the Maricopa County Sheriff. For these two reasons there are no other plans within any of the cities for expansion of their jail facilities.

The demand for jail facilities is a complex one. It is a function of several factors. These include but are not to be limited to the juvenile system within the area, the general feeling of the community towards crime and the corresponding willingness to fund new correctional facilities, the age structure of the population and the size of the population itself. In 1987, Maricopa County opened a new jail. This facility was to be gradually filled over the next 3-5 years but it reached maximum occupancy within a year. Recently, tent cities have been constructed to relieve the demand pressures on the existing facilities. The juvenile system of the area is considered to be a key in projecting the demand for jail facilities.

Known plans by the County for new correctional facilities include only one facility. In the City of Peoria, the North West Maricopa County Complex is proposed for the 40 acre property adjacent to the Peoria Municipal buildings located at 8401 W. Monroe, TAZ 306. A Juvenile Detention Center will be included within this complex. It is expected to be built sometime before the year 2000. We have assumed that one-fourth of this site is used for a new suburban-type correctional facility. Model Input: RAZ 239, 160 Inmates.

3.2 SEASONAL POPULATION

RV and Mobile Home Parks. In the Town of Gila Bend there is a potential site for an additional mobile home park. It is on the east side of town, to the north of I-8 and to the south of Highway 85. It would have a capacity of 30+ lots. Model Input: RAZ 331, 30 Lots.

In the Town of Surprise expansion of the Happy Trails RV Park is proposed. This is a resort that includes two golf courses. It is located at 17200 W. Bell Rd., TAZ 145. Completion is scheduled for 1994. Model Input: RAZ 232, 200 Lots.

In the Town of Wickenburg there has been an informal proposal for a 40+ acre mobile home park. The site is located adjacent to the American Inn on the east side of Highway 60. No application has been submitted yet and development is likely to be 2-3 years away. Model Input: RAZ 201, 600 Lots.

Other Seasonal Housing. Of the twelve retirement communities within the county, only five are completed. The remaining seven have over 19,000 unbuilt residential units. Construction is just beginning on a 10,000 unit resident community near Goodyear by the developers of Sun Lakes. No other plans of expansion or development of other retirement communities within Maricopa County are known at this time. The number of units yet to be constructed in each development, and the RAZ where each development is located is shown in Table VII-1.

3.3 TRANSIENT POPULATION

Hotels, Motels and Resorts. In the City of Avondale there is potential for a resort in the vicinity of Phoenix International Raceway, TAZ 1161. Development is dependent on the delivery of sewer and water facilities as well as the construction of a bridge crossing on the Gila River. There also is potential for hotel/motel development in the freeway corridor area. This will be ancillary to business and industrial activity. Model Input: RAZ 324, 200 Units.

In the Town of Buckeye, an 80-unit motel is proposed for the junction of Highway 85 and Oglesby Road. Timing is dependent upon construction of a water supply line to the site. It is interesting to note that much of the population of Buckeye is seasonal or transient, following the winter work force demands of the local cotton harvest. Model Input: RAZ 277, 80 Units.

In the Town of Cave Creek, TAZ 5, a resort is proposed. The resort will have 200 beds and a golf course. The golf course is already in place and building construction will be completed within the next five years. Model Input: RAZ 207, 200 Units.

The City of Chandler is seeking specific proposals for a hotel downtown, or in the I-10 corridor area. This would be a 200 unit hotel that the city feels will likely be constructed within the next 5-10 years. Additional demand for hotel accommodation could also be stimulated by the growth of activity on adjacent Indian land regarding casino gambling and the expansion of industrial activity near Queen Creek Rd. and I-10. Events at Compton Terrace will also stimulate need for hotel accommodations in the area. Model Input: RAZ 315, 200 Units — wait for more definite information on development at Queen Creek & I-10.

In the Town of Fountain Hills sites have been designated for resorts but none have been developed. The corner of Saguaro Drive and Shea Blvd., TAZ 265 or 334, is likely to be the first area developed and will be about 50 rooms. This will be within the next five years. Model Input: RAZ 250, 50 Units.

In the Town of Gila Bend a 60 room motel has been refurbished and will reopen in October 1993. It is located at 1046 Pima Street, TAZ 1380. Model Input: RAZ 331, 60 Units.

In the City of Gilbert there are several potential hotel development sites. On the south west corner of Warner and Gilbert, TAZ 1153, is a 15 to 20 acre site for a possible 200 room hotel. On the north west corner of McQueen and Guadalupe, TAZ 1074, is a 300 acre parcel to include a hotel, residential development and a golf course. Also on this corner but to the south east, TAZ 1106, is a recreation facility called Arizona Ski Springs. This facility is considering expansion to include 200 time share casitas. Development of a theme park is also under discussion. The park would be located east of Val Vista. Hotel development is possible as a spin off from this activity. Model Inputs: RAZ 318, 200 Units; RAZ 311, 400 Units.

In the City of Glendale there is a possible long term expansion of the Sage Hotel. This hotel is located downtown at 5949 NW. Grand Ave., TAZ 371. The North Valley Specific Plan calls for the development of a Hotel at the Arrowhead Mall now under construction at Bell Road and 79th Ave, TAZ 156. Model Inputs: RAZ 258, 100 Units; RAZ 222, 200 Units.

In the City of Mesa there is a hotel development proposal in conjunction with the existing Hilton at Alma School and the Superstition Freeway, TAZ 1016. Expansion will include an additional 256 rooms, a conference center and meeting rooms. Development is likely to be in the next 5-10 years. There also is potential hotel development near the Superstition Springs Mall. Model Input: RAZ 309, 256 Units.

In the Town of Paradise Valley there are several proposals to expand existing resorts, and to develop new ones. A 500 room resort is proposed to include a 9 hole golf course on the corner of Indian Bend and Scottsdale Rd., TAZ 388. Mountain Shadows at 56th St. and Lincoln Dr., TAZ 420, is expected to expand with 50-75 additional rooms. Camelback Inn at 54th St. and Lincoln Dr., TAZ 420, is expanding with an additional 100-150 rooms within the next three years. A potential 20 acre site exists at Scottsdale Road and Hummingbird Lane, TAZ 387. Hotel development is expected to occur within the next 5-10 years on this site. Model Inputs: RAZ 262, 525 Units (3 hotels); RAZ 263, 500 Units.

In the City of Peoria there is hotel development planned in conjunction with the PAD for the Boswell Hospital Annex. A potential hotel location also exists in North Peoria in association with the development of the Arrowhead Regional Mall. Model Input: None - no firm plans.

In the City of Phoenix there is potential for hotel development in the downtown area generated by the Civic Convention Center. Possible locations include 2nd/3rd St. north of Jefferson, adjacent to City Hall, TAZ 756. Model Input: RAZ 275, 500 Units.

In the City of Tolleson there are plans by Westcor for a high rise hotel on 40 acres to the north of the intersection of I-10 and 99th Ave, TAZ 598. A syndicate has also proposed development to the south of this intersection, TAZ 674, on 150 acres. This would include business hotel and motel facilities in conjunction with industrial and highway related development. Model Input: RAZ 273, 500 Units (2 hotels).

4.0 PROJECTION METHODOLOGY RESEARCH

The methodology research for RAZ-level special population projections is consistent with the methodology developed for the County-level projections in that it divides each special population group into its contributing components. For example, we attempted to subdivide Group Quarters population into military, institutional, college, nursing home, and "other" components. The basic approach was to determine factors that seem to drive the current distribution of each component activity, and apply them to land use information to project future activity.

The fundamental steps of implementing this approach were:

- 1) Develop a set of locational factors suitable for predicting the location special populations;
- 2) Analyze the locational factors with existing special populations to develop relationships;
- 3) Identify appropriate land uses for each special population component;
- 4) Calculate the relationship of population to land area for each population component; and
- 5) Produce a system / format to implement the projections.

The balance of this chapter transmits the effort undertaken by ESG to accomplish each step in the approach. The descriptions focus on methodology rather than actual results, as we expect that most information would be updated / refined prior to official projections being developed.

4.1 SPECIAL POPULATION LOCATIONAL FACTORS

The locational factors developed by ESG for analyzing special population groups included some commonly used by MAG, such as population and employment density indicators, as well as some new measures including:

- Recreation Index
- Major Retail Index
- Airport Index
- Hospital Index

Each of these factors were developed by compiling an inventory of known attractors, and then creating indices for each RAZ based on aggregated TAZ distance-weighted measurements. The measurement varied by factor.

Recreation. In the case of the Recreation Index, data for attendance at major places of interest from "Inside Phoenix" was used to calculate the locational factor. As Table VII-2 shows, this information provides the annual attendance at a number of attractions throughout Maricopa County. Each of the attractions were assigned an X and Y coordinate, and then accessibility indices for TAZs were calculated using distance (straight-line) as an inverse weighing factor.

Retail. Like recreation, the Retail Index was calculated using data for major retail centers around Maricopa County. Square footage was used as the measurement of the size of each retail attractor (see Table VII-3). Again, each attractor was coded with an X & Y coordinate and indexes were calculated using distance as an inverse weighing factor.

Airport. Commercial passenger enplanements at Sky Harbor International Airport were used as the "size" indicator for this attractor. Straight line distance was again used to determine the density index. As / if other airports institute commercial service, they could be added to the index calculation in the same manner.

Hospital. The number of beds at each facility was extracted from the inventory of hospitals prepared as part of the first phase of this task. Through that process, X & Y coordinates had already been assigned to each facility. Straight line distance was again used to determine the density index.

4.2 LOCATIONAL RELATIONSHIPS

In this step of the methodology development for special populations, the locational factors detailed above, along with 1985 levels for each special population group, were analyzed to develop locational equations for each special population component. The Microfit statistics package was used to perform ordinary least squares (OLS) regression analysis based on adjusted White's heteroscedasticity-consistent standard errors. The following sections describe the results of that analysis for each special population component.

The note that the purpose of this part of the analysis was to explore options for predicting the distribution of special populations. It may not be possible, or practical, to develop projections of all the independent variables used in the following locational relationships. Nonetheless, some of the relationships have good predictive power, and it should be possible to develop proxies for many of the independent variables which could be projected.

4.2.1 Group Quarters

The analysis of the location of Group Quarters populations was implemented using each of its component elements. However, in the process of analyzing the location of the elements it was found that, by their nature, they are too concentrated to be evaluated using statistical methods. These group quarters elements include military, college dormitory, and jail components of Group Quarters population.

Simply put, the total number of sites was too small to be used as statistical sample. The only locational variables that were shown to be significant in predicting the 1990 distribution of these activities was the distribution of the activities in 1985. Therefore, a different approach was used to project growth for these elements of group quarters population. In short, the approach used was to incorporate identified known additions into the appropriate time

periods, and allocate the balance to RAZs on a pro rata basis. For the time periods after 2000, all growth was allocated on a pro rata basis.

Note that some success was obtained in analyzing the distribution of group quarters population in nursing homes using statistical analysis. The analysis showed that population density and hospital proximity were both highly significant in predicting the distribution of population in nursing homes (both variables had T-Ratio's in excess of 2.00).

Seasonal Population. As per group quarter population, the distribution of seasonal population was not successfully analyzed using statistical analysis. The analysis showed that the distribution of seasonal population is positively influenced by population density, and negatively influenced by employment density. However, this would be true on any population group. In general, we found that the location of growth in this population group was most influenced by the existing seasonal population, and by large-scale retirement developments.

The methodology developed to project seasonal population was divided into two segments, one for RV's and Mobile Homes, and another for "other housing". However, the growth in each segment was forecast based on known additions, and a pro rate distribution of the balance as for group quarters population.

Transient Population. The only success in using the locational factors to predict the distribution of special population was for the components of transient population. As described above, transient population is divided into four components: leisure, group, business, and other. The analysis for each component is as follows.

- **Leisure.** The most significant predictor of leisure transient population was the distribution of total transient population in the time period before. In addition, the Retail Index was found to be positively significant in predicting the distribution of leisure transient population, while the Recreation Index was found to be negatively significant. At first the negative sign on recreation seems counter-intuitive for leisure, however the index was developed using large, centrally located attractions (Zoo, museums, etc). Therefore, the suburban location desired by leisure travelers, separates them from "major" attractions.

The resulting equation had an adjusted R-squared (R-bar Squared) of 0.908, meaning that it explained about 90 percent of the variation in the level of leisure transient population. Considering that the data was cross-sectional, and that the distribution is ultimately constrained by land use, this result is acceptable. Using the independent variables developed by ESG, the locational equation developed was as follows:

$$\text{Leisure Pop. 1990} = 0.3838 * \text{Trans1985} + 0.0197 \\ * \text{Retail Index} - 0.0754 * \text{Recreation Index} + 19.20$$

- **Group.** Population Density was found to be positively significant in predicting the distribution of group transient population, while employment density was found to be negatively significant. These findings served to confirm the assumption made by ESG in developing County-level forecasts

that this component of transient population would most closely resemble the leisure component. The resulting equation had an adjusted R-squared (R-bar Squared) of 0.68, meaning that it explained about 68 percent of the variation in the level of leisure transient population. Considering that the data was cross-sectional, and that the distribution is ultimately constrained by land use, this result is acceptable. Using the independent variables developed by ESG, the locational equation developed was as follows:

$$\begin{aligned} \text{Group Pop. 1990} &= 0.3122 * \text{Trans1985} + 0.5824 \\ &* \text{Pop. Density} - 1.0691 * \text{Emp. Density} + 5.74 \end{aligned}$$

- **Business.** Employment and airport accessibility were both found to be positively significant in predicting the distribution of business transient population. Although, like the other two components of transient population, the distribution of transient population in the previous time period was the more significant indicator. The resulting equation had an adjusted R-squared (R-bar Square) of 0.895, meaning that it explained about 90 percent of the variation in the level of leisure transient population. Considering that the data was cross-sectional, and that the distribution is ultimately constrained by land use, this result is acceptable. Using the independent variables developed by ESG, the locational equation developed was as follows:

$$\begin{aligned} \text{Business Pop. 1990} &= 0.2733 * \text{Trans85} + 0.2639 \\ &* \text{Emp. Density} + 0.0458 * \text{Air Index} + 6.52 \end{aligned}$$

- **Other.** In the best analysis for "other" transient population, recreation accessibility and leisure transient population were found to be positively significant in predicting the distribution of leisure transient population. However, the resulting equation had an adjusted R-squared (R-bar Squares) of just 0.29, meaning that it explained only about 29 percent of the variation in the level of "other" transient population. This is indicative of this group consisting of a wide variety of type of visitors. It was determined, therefore, to geographically distribute these visitors as a function of the other three components of transient population.

Note that when it comes time for MAG to implement this methodology as part of it update process, it will be necessary to re-estimate ALL the equations described above to be consistent with its own set of independent variables. However, the variables important to each equation could be expected to remain unchanged.

4.3 LAND USE CATEGORY SELECTION

Once locational equations were developed, land use information was examined to determined how it could best be used to further direct the distribution of the special population groups. As with the statistical analysis, the success of this effort was mixed. The

"MAG High" land use categories were reviewed to identify land uses corresponding to the special population groups. This set of categories was chosen since the relationships between land use categories across all jurisdictions has been determined. Unfortunately, we were unable to identify corresponding land uses for many of the special population groups.

In the case of group quarters populations, only the hospital, schools and government land use categories appeared to be at all appropriate, and even they seemed too broad to use in projecting most components of group quarters population. Therefore, it was necessary to develop the RAZ-level projections for nursing homes without using land use information.

In the case of seasonal population, no specific land use categories were identified as being suitable for the allocation of growth. However, as discussed above, all three portions of seasonal population, Mobile Homes, RVs, and "other" housing, should be projected based on known additions, and the existing distribution. Further, the component of seasonal population residing in other types of housing should be based on the Census estimate of the number of units held for seasonal, migrant, and other use. This portion of units by type should be determined for each RAZ, and applied to projected housing inventories to project seasonal population in other unit types.

Finally, for transient population, the Hotel/Motel and Resort land use categories were chosen from the MAG high land uses. These land uses are obviously quite suitable for use in projecting the distribution of transient population.

4.4 LAND USE DENSITY & CONSUMPTION

Where land use categories were found that could be used to help project the distribution of special populations, it was necessary to develop density assumptions to correlate population and land area. Land use density estimates were prepared for most components of the special population groups so that the information would be available for future use. Each density estimate is based on a sample of the generators in each category obtained from the inventory compiled by ESG.

The land use density assumptions developed for this task are shown applied to County-level growth in each special population component to project the land to be consumed. Note that growth in each special population component can vary significantly, and somewhat erratically from time period to time period. This is due to the fact that the projections for each component are a function of growth in a specific subset of the population in Maricopa County, and across North America. In particular, the special population components based on older people, resident population in nursing homes and seasonal population, show rapid growth at the end of this century and early next century due to the age structure of the baby boomers.

Group Quarters. Population density assumptions, and land use absorption by group quarters populations are summarized in Table VII-4. A detailed description of these estimates and projections for each component follows.

- **Jails.** Because of the wide disparity in population densities between the two downtown facilities and the outlying facilities, two sets of density ratios were developed. Outlying facility population density ratio of 15.56 persons per acre was developed using the average of:

- The three facility Durango complex - 2,364 persons on 95 acres
- Perryville - 2,176 persons on 200 acres
- New River - 1,585 persons on 145 acres

Downtown facility population ratio was found to be 442.80 persons per acre, based on the Madison Street and First Avenue facilities which house 2,214 persons on 5 acres of land.

Adding the population of the downtown facilities to those in the outlying area (juvenile centers not included), showed the April 1993 population in jails at 8,808, implying that 25 percent of the total number of prisoners were housed in the high-density facilities downtown. In calculating acreage needed for future use, three-fourths of the increase in population was assumed to occur in outlying facilities (15.56 persons per acre), and one-fourth was assumed to occur in downtown facilities (442.80 persons per acre). Using these assumptions, about 8.3 acres of downtown government land, and 709 acres of outlying government land will be absorbed for use by jails between 1990 and 2040.

- **College Dormitories.** The college dormitories at A.S.U. were found to house about 66 persons per acre. This is based on an average of 44 rooms per acre, with an average occupancy of 1.5 persons per room. Accounting for the amount of space currently vacant in existing dormitories, this population density would imply absorption of about 113 acres of land for dormitories between 1990 and 2040.
- **Nursing Homes.** A sample of medium-sized (103 to 180 room) nursing homes built since 1984 were used to derive population density estimates. For each facility acreage information was obtained either from phone survey or assessor's records. The facilities were found to have 27.6 beds per acre. This would translate the projected county-level population in nursing homes into absorption of about 709 acres of land between 1990 and 2040.

Seasonal

- **Mobile Homes.** A sample of 17 mobile home parks built since 1984, dispersed around the County but primarily in Mesa and Phoenix, were used to derive an average of 6.63 units per acre. As shown in Table VII-5, by dividing the projected population in mobile homes by 2 person per unit and adjusting for occupancy, this population density would imply absorption of over 3,400 acres of land between 1990 and 2040.
- **Recreational Vehicles.** A sample of 7 recreational vehicle parks built since 1984, dispersed around the County but primary located in Mesa, were used to derive an average density of 12.84 spaces per acre. As shown in Table VII-6, by dividing the projected population in RVs by 2 persons per units and adjusting for occupancy, this population density implies absorption of over 2,200 acres of land between 1990 and 2040.

Transient. A sampling of a mixture of hotels, motels, and resorts, all built since 1984, was used to derive an average density of 43.97 rooms per acre. Peak occupancy rates and population were used to derive an overall average population per room. This average is expected to trend downward slightly over time with the aging of the population. It ranges from 1.39 in 1990 to 1.28 in 2040. As shown in Table VII-7, these population per room and population density assumptions imply absorption of over 300 acres of land between 1990 and 2040.

4.5 PROJECTION MODEL OVERVIEW

The projection model developed by ESG to implement the RAZ-level projections of special population utilizes a series of Microsoft Excel spreadsheets to bring together independent locational variables, location equations, and land use data. In the case of components of special populations where this approach was not applicable, other growth assumptions (known generators and additions to known generators) are coded into RAZ-oriented spreadsheets and combined with the others to project total special populations by RAZ.

In general each spreadsheet is organized into four or five sections horizontal across the top, with RAZ number running down the first column. Other components of the spreadsheets are as follows:

- The first section includes the 1990 RAZ-level estimates for the particular variable. Often this included the figure developed by MAG, in addition to estimates prepared by ESG using the inventory information.
- The second section contains the independent variables used in the projection for the specific component of special populations, if any. These include the accessibility indices described above.
- The third section is optional, as it contains land use information used in the RAZ-level allocation. Only the seasonal and transient non-resident spreadsheet models contain this information.
- Section four calculates raw attraction scores for each RAZ based on the regression equations for that variable, and the independent variables included in the first section. The section also includes another column for these "scores" where thresholds and weighing factors are sometimes applied.
- The fifth sections contains known additions to the particular special population group. These additions are allocated to growth in the 1990 to 1995, and 1995 to 2000 time periods.
- The last section translates the raw scores into projected population by time period (five year increments from 1995 to 2040). These data are benchmarked to the county-level growth projections for each component of special populations.

The following sections list and briefly describe the spreadsheet provided for each special population group.

Group Quarters. The group quarter projections are implemented using six spreadsheets:

- GrpQtr90.xls
- Jails.xls
- Military.xls
- Dorms.xls
- Nursing.xls
- GroupOut.xls

GrpQtr90.xls is the spreadsheet developed to estimate RAZ-level group quarters population by type. Inventory-based estimates by ESG are used to distribute MAGs/Census total group quarters population among the components. This spreadsheet should be replaced by actual census data aggregated to RAZs.

Jails.xls, Military.xls, Dorms.xls, Nursing.xls are RAZ-oriented spreadsheets simply used to incorporate known additions, and pro rata distributions for these components of group quarters population. As discussed above, none of these components lend themselves to projection on the basis of statistical relationships. However, it is still worthwhile to project the components of group quarters, and aggregate them to total group quarters population. Assumptions for Military and Jail populations have been discussed above, and assumptions for Dormitory populations are shown in Table VII-8.

GrpQtrFU.xls combines the result of the four spreadsheet above, calculates "other" group quarters based on the distribution of the first four contributors, and added all of them together to yield total group quarters projections by RAZ.

Seasonal. Seasonal population in mobile homes and RVs at the RAZ level is projected in Seasonal.xls. This spreadsheet calculates both mobile home and RV population together. The form of the spreadsheet is as described above in the general description section. Seasonal population of "other" housing is projected in SeasOthr.xls. This spreadsheet incorporated known additions to seasonal housing (based on retirement area inventory). The balance of growth is allocated to RAZs based on projected total inventory, and 1990 vacancy status data. This approach could be further refined in subsequent projects by projecting vacancy status data for each RAZ over the 1995 to 2040 projection period.

Transient. The spreadsheet Transnt.xls implements the RAZ level projection of transient non-resident population. The structure is described in the general section, except that multiple locational "scores" are calculated within one spreadsheet, corresponding with the three primary components of transient population: leisure, group and business travels. It was necessary to combine these into a weighted composite score by RAZ because the land uses, hotel/motel and resort, would both contain all three type of travelers.

5.0 RAZ PROJECTIONS

Tables VII-9 through VII-12 show the RAZ-level projections of resident group quarters, non-resident seasonal, and non-resident transient populations respectively. As noted in the introduction to this paper, these projections are provided for illustrative purposes only, and are not approved for official use.

VIII. OTHER DATA REQUIREMENTS

1.0 INTRODUCTION

This working paper and its associated materials have been prepared to identify and inventory major land use projects and other development issues. Specifically, this task consists of three components:

- Planned Area Developments
- Redevelopment
- Land Costs

This report includes a description of data collection and analysis efforts, methodology used to enhance and supplement the base data, and summarizations of the data collected. Also included are appendices containing a large-scale boundary map of planned area development sites, an alphabetical listing of planned area developments, and detailed maps of redevelopment areas and supporting documentation.

2.0 PLANNED AREA DEVELOPMENTS: EXISTING, PLANNED, AND PROPOSED

Planned Area Developments are characterized by a unified overall master plan and frequently include the types of community and other non-residential space found in small towns. While typically used for residential developments, this form of unified planning is sometimes used for non-residential developments. Both types of development, residential and non-residential, have been included in this study.

Base data for planned area developments was taken from studies by Canyon Research (Planned Area Developments) and the Maricopa County Department of Planning and Development (Large-Scale Developments). Site and development plans were used, when available, to increase the level of specificity and accuracy regarding separate types of land usage within a development when such data was not present in the base studies. City planning personnel were contacted regarding unclear or conflicting information, with planning department files referred to in some instances. Since large-scale development plans tend to evolve over time, efforts were made to utilize the most current plans known.

The location and boundaries of these 171 planned and proposed developments can be found on the Appendix B metropolitan area map. The database record used to organize the information about each development is outlined in Figure VIII-1. Note that the record includes information on the total number of units by type, and the acreages. Also included are estimates of the amount of built and vacant acres by land use.

In instances where the base studies used marketing terms (such as casita), or used terms interchangeably (patio home and townhouse, townhouse and condominium), such properties were categorized based on building structure, density, and zoning, taking into consideration the location and character of the individual development involved. Also utilized were city staff, descriptive text about the developments, and the texts, The Language of Zoning (Michael Meshenberg, Planning Advisory Service of the American Society of Planning Officials), and The VNR Real Estate Dictionary (David Brownstone and Irene Franck). For the purposes of this study the general definitions used were:

- Single family: detached units;
- Patio home: detached units at greater density, approximately 5-7 units/acre;
- Townhouse: single family attached, with ownership of the underlying property, approximately 8-12 units/acre;
- Condominium: multifamily with ownership of the unit only;
- Apartment: multifamily without individual ownership, higher density than condominiums.

For those developments where information was not available on specific divisions of land usage by type, the information was allocated, to the extent possible, based on proportions of land use by type present in other developments of similar size and general characteristics. For developments where this method was not feasible, division of land usage by type was based on the location and characteristics of the development and estimated development intensity. In all instances where estimations were necessary consideration was also given to the development's location, both geographically and in reference to surrounding development, and the target market planned, when such information was available.

Summarized data for the 171 planned area developments included in this study is contained in the following tables:

Table VIII-1 shows the division of residential components of these developments and the number of built and unbuilt units. This table shows constructed housing units are only **16%** of the total planned. Also shown is the fact that single family detached units (single family plus patio homes) comprise **63%** of the total units planned.

Table VIII-2 shows the divisions of non-residential development and acreage which is undevelopable or set aside for open space, parks, and golf courses, and the amount of acreage currently utilized. It can be seen that development of commercial acreage lags far behind residential development.

3.0 REDEVELOPMENT

Redevelopment areas are identified by cities as being sub-standard in character or designated as a redevelopment area due to economic, geographic, or other constraints. Base information for this component was taken from interviews conducted with planning department representatives of Maricopa County and of all cities and towns within Maricopa County.

A brief description of the identified redevelopment plans is contained in Table VIII-3. The accompanying maps, found in Appendix C, show the geographic outlines of each identified redevelopment area. Following is a summarization of the redevelopment plans for those cities and towns which have such areas designated.

Town of Buckeye. The majority of the downtown area has been designated a slum and blighted area by the Town of Buckeye. The town has received CDBG funds to assist in the refurbishment and upgrading of this area. Proposed improvements include street and sidewalk modification, and residential and commercial property refurbishment.

City of Chandler. The single redevelopment area in the City of Chandler covers 1920 acres and includes the downtown commercial area. Redevelopment plans include recruitment of retail development, upgrading existing commercial frontage, use of CDBG funds for rehabilitation of single family residential properties, and private redevelopment of small, municipal properties including a 40-80 acre parcel at the southwest corner of Chandler Boulevard and Arizona Avenue. This parcel is proposed for approximately 100,000 square feet of commercial and office uses, with a "farmers market", forecast for construction between 1995 and 2000.

Town of Gilbert. A downtown redevelopment plan was adopted by the Town of Gilbert in 1991. The primary focus of the plan is the improvement and refurbishment of existing residential and commercial properties, including exterior treatment, internal servicing, and streetscaping. The town is also forming an economic development policy to encourage commercial growth in the downtown area.

City of Glendale. The designated redevelopment area surrounds and includes the downtown district. The City of Glendale is supporting public works upgrading and policy updating to promote reinvestment and redevelopment. The redevelopment policies call for mixed commercial and residential uses and currently is approximately 30 percent complete.

City of Mesa. Three forms of redevelopment are currently in place in the City of Mesa: site specific redevelopment, infill development in older neighborhoods, and the Town Center redevelopment area. The partially implemented Town Center plan has been in place for several years with the purpose of encouraging the upgrading and redevelopment of the downtown business core.

City of Peoria. A redevelopment plan for the northern area of the City of Peoria was prepared in the fall of 1992. The plan addresses zoning inconsistencies, traffic circulation, land use changes, and servicing problems. The plan proposes construction of a baseball stadium at Bell Road and 75th Avenue, the "North Valley Power Center" at Bell Road and 90th Avenue, with office, commercial, and residential uses to the south.

City of Phoenix. There are currently five redevelopment areas active within the City of Phoenix:

- **Government Mall.** This plan calls for the consolidation of land uses and the refurbishment of existing properties. Mixed use development characterizes the area north of Van Buren Street while commercial development and government facilities characterize the area south of Van Buren Street.

- **Sky Harbor Center.** This plan was adopted in 1985 and calls for the removal of slum properties and the construction of airport support uses, a "high-tech" business park, industrial and distribution uses with neighborhood services on the eastern portion of the area.
- **Camelback East.** Planned for completion by 2015, this plan is designed to encourage development of a mixed use central core with retention of single family residential uses while resolving traffic conflicts and improving public works facilities.
- **Phoenix Arts District.** This plan identifies a potential gross building area of 2.7 million square feet with 400,000 square feet of arts-related retail and community uses.
- **Phoenix Indian School.** The redevelopment of this Central Avenue property is planned for joint private and public uses but conflicting interests make timing and details uncertain.

Town of Queen Creek. CDBG funds have been approved for the financing of a sewage treatment plant and infrastructure to service the 500-600 acre area surrounding and including the existing town center. The funding, which also provides for future residential and commercial development, could be in place by 1995-2000.

City of Scottsdale. There are currently two redevelopment areas designated in the City of Scottsdale:

- **Waterfront.** This plan calls for the modification of commercial land use for waterfront-oriented development, taking advantage of the location adjacent to the Arizona Canal. The plan calls for mixed-use development with service commercial and public uses, indoor and outdoor entertainment facilities, restaurants, with pedestrian orientation and bridges. While no formal status is in place, suggested timing includes: 55,000 square feet of entertainment use and general retail, 90,000 square feet of specialty and museum retail, and 550,000 square feet of office development in place by 2005; a 300 room hotel completed between 1996-2000; 900 multifamily/condominium units by 2000.
- **Southeast Downtown.** This partially completed plan encourages the development or refurbishment of the mixture of uses characterizing the area. Existing uses include the Civic Center and City of Scottsdale government offices, hospital and medical office space, and a newly completed major league baseball stadium. The plan is divided into eight sub-areas with completion expected in 2015-2020.

Town of Surprise. CDBG funds have been approved for the construction of a regional water and sewage treatment facility. Construction, to be completed by 1996, is expected to stimulate major development in the 700 acre area. A 60 acre parcel on the northwest corner of Dysart Road and Peoria Avenue has been designated for industrial development, pending servicing and sufficient infrastructure.

City of Tempe. There are two redevelopment areas active:

- **Downtown.** This 120 acre historical district has been in the redevelopment process for several years and is 70 percent completed. The area includes office, commercial, entertainment and restaurant uses, and residential property. Completion is expected by 2005-2010.
- **Apache Boulevard.** The City of Tempe is encouraging private commercial and industrial development with improvements including street improvement, lighting, and landscaping. Completion is expected by 2005-2010.

Town of Wickenburg. A specific plan is currently being prepared for the redevelopment of the downtown and surrounding area of 140-160 acres. Land uses include mixed residential, commercial, and public open space. Completion is expected by 2005-2010.

4.0 LAND COSTS

The final product of the Other Data Requirements task is an estimate of land costs/values for book-map areas in Maricopa County. The Assessor's Full Cash Values of Land for each parcel, from the Parcel Database developed for Task 6, were aggregated to determine the total value of the land in each book-map. This value is then divided by the total land area of each book-map, as derived from the book-map map also developed as part of the work for Task 6.

The resulting values, areas, and values-per-acre estimates for each book-map are provided in the "LAND VALUES DATABASE." This database includes one record for each of the 6,028 book-maps in Maricopa County.

A summary of the database appears in Table VIII-4.

Maricopa County

Municipality	Map Number	Redevelopment	Estimated Configuration
Glendale	203	Downtown area from Orangewood Ave. to Maryland and 51st to 63rd Aves., TAZ 370, 371, 372, 400, 401 & 402. Mixed use residential and retail uses. Also, commercial office uses. Redevelopment is 30 percent complete.	960 acres Mixed use
Guadalupe		None	
Litchfield Park		None	
Mesa	204	Town Center area for refurbishment of existing residential uses and small scale redevelopment. Located from E. of Country Club Dr. to W. of Mesa Dr. and N. of University Dr. to S. of Broadway Rd., TAZ 847-851, 898-905 & 964-966. Future uses to include retail, commercial and office space.	830 acres Mixed use
Paradise Valley		None	
Peoria	205	North Peoria from Bell Rd. to Thunderbird Rd. and 91st Ave. to Glendale/Peoria border, TAZ 182, 183 & 208. Refurbishment and public works of mixed use areas. Also, construction of baseball stadium for spring training and other seasonal uses.	2,200 acres Mixed use
Phoenix	206	Government Mall between Fillmore and Harrison and 7th Ave. and 19th Ave. to Grand Ave., TAZ 686, 745 & 748. Government offices south of Van Buren. Local retail along Van Buren with residential improvement areas to the north.	460 acres Mixed use
	126	Sky Harbor redevelopment area at 16-24th Sts. and Jefferson to S. P. Railway, TAZ 763 & 765. Removal of slum property and redevelopment for industrial and commercial in commerce park areas.	960 acres Ind., Comm., Off. & Open uses

TABLE VIII-3 (Continued)
Redevelopment Activity
Maricopa County

Municipality	Map Number	Redevelopment	Estimated Configuration
Phoenix	207	East Camelback redevelopment area located from 16th St. to 28th St. and Colter St. to Campbell Ave., TAZ 458, 460, 461, 499, 500 & 502. Mixed use central core and retention of single family while resolving traffic conflicts and improving public works and use areas. Completion by 2015.	720 acres Mixed use
	208	Phoenix Arts District along Central Ave. from Oak to Moreland, TAZ 622, 623 & 625 for development of 2.7 million SF of offices and .4 million SF of arts related retail and commercial use.	60 acres Comm. & Off. uses
	209	Indian School area on north east corner of Indian School Rd. and Central Ave., TAZ 496, For reuse as office, commercial & open space, mixed use residential and retail on 108 acre site. Timing is unknown.	108 acres Mixed use
Queen Creek	210	Old urban area located at Ocotillo Rd. and Ellsworth Rd., TAZ 1240, 1241, 1254 & 1255, subject of CBD grants for servicing, 1995-2000. Future uses to include residential and local commercial/retail as part of large scale development of adjacent land areas.	500-600 acres Mixed use
Scottsdale	211	Waterfront area along canal banks from 88th St. & Indian School to Highland, TAZ 516, 517 & 518. 90 acres to be reused for 55,000 sq. ft. entertainment and retail, 300 room hotel, .5 million sq. ft. office, 500-800 residential units. Timing of plan phased out over 1996-2005.	90 acres Mixed use
	212	SE Downtown area from Miller Rd. to Scottsdale Rd. and Indian School Rd. to Earl Rd., TAZ 578. Mixed uses are of civic and government offices, hospitals and medical related offices and clinics, recreation stadium and residential. Buildout planned for 2015-2020.	160 acres Mixed use

TABLE VIII-3 (Continued)
Redevelopment Activity
Maricopa County

Municipality	Map Number	Redevelopment	Estimated Configuration
Surprise	213	Old town Surprise is in redevelopment, area from Bell Rd. and Dysart Rd. to Greenway Rd. and El Mirage Rd., TAZ 178. New servicing system to be installed by 1996, expected to stimulate major growth in the planning area.	700 acres Mixed use
Tempe	214	Downtown area from 1st St. and S.P. Railway to University Dr. and College Ave., TAZ 837, 838 & 839. 70 percent complete. Reuse for refurbished retail, new office and commercial space including mixed use development for residential, retail and office uses. Completion expected by 2005-2010. Apache Blvd area from Price Rd. to Mill Ave., TAZ 881-887. Mixed use commercial and industrial area. Streetscape and public works to be limited. Redevelopment by private concerns to be encouraged. Timing for completion by 2005-2010.	120 acres Mixed use
Tolleson		None	
Wickenburg	216	Downtown area from Adams St. and Cochise St. to Sol's wash and the Hassayampa river, RAZ 201. 140-160 acres for development of residential (MF & SF), commercial, retail and open space. Timing in 2005-2010 time period.	140-160 acres Mixed use
Maricopa County		None. Concern as to scope of development plans of the outlying municipalities, especially in areas of environmental sensitivity, upper Sonoran Slopes area in north Phoenix and Peoria.

PARCEL DATABASE

DATA DICTIONARY

PARCEL DATABASE DATA DICTIONARY

Field Name: **ACRES**
Field Type: real
Field Width: 10
Field Format: F10.2
Source: MetroScan or Fractional Acreage Database or Other

Description

The acres field shows the size of parcel in acres. This information was obtained from assessor's information obtain through MetroScan, from a database of Fractional Acreages stored in the original Parcel Database, or from some other source stored in the original Parcel Database.

Field Name: **ACRESFLG**
Field Type: character
Field Size: 2
Source: MetroScan or Other

Description

The acres flag field indicates the source of the acres data contained in the ACRES field. The acres flag code is listed below:

<u>Code</u>	<u>Description</u>
MS	MetroScan
MW	Other — Originally done by Mountain West
Blank	No acreage data available

Field Name: **ADDRESS**
Field Type: character
Field Size: 34
Source: MetroScan or original MAG Parcel Database

Description

Site addresses included in the ADDRESS field are converted into a standard format. The standard site address is composed of the street number, street direction, street name, and street suffix. ADDRESS was always derived from MetroScan unless blank, and an address was provided on the old parcel database.

Field Name: **ASSPCT**
Field Type: real
Field Width: 8
Field Size: F8.2
Source: MetroScan

Description

This field contains the assessment ratio applied to land and building values to calculate assessed value. Assessment ratios vary by land use type, the most common are as follows:

<u>Rate</u>	<u>Land Use</u>
10%	Residential Property
16%	Vacant Land
25%	Commercial Property

Field Name: **BATHS**
Field Type: character
Field Size: 2
Source: MetroScan

Description

This field shows the number of bath fixtures with a total of 3 fixtures per bathroom: toilet, sink, and bath. A property with 2 full bathrooms would contain 6 in the field.

Field Name: **BLDGFCV**
Field Type: real
Field Width: 15
Field Size: F15.2
Source: MetroScan

Description

This field contains the full cash value of any improvements on the parcel. It is expressed in dollars.

Field Name: **CITYCODE**
Field Type: character
Field Size: 2
Source: Tax Area Code

Description

The city code consists of 2 characters and was assigned based on tax area codes. Thus, this code would indicate the jurisdiction in which a parcel is located, which may be different than its mailing address city. The city codes are listed below.

Code Description

AV	Avondale	GI	Gilbert	QC	Queen Creek
BU	Buckeye	GL	Glendale	SC	Scottsdale
CA	Carefree	GO	Goodyear	SP	Surprise
CC	Cave Creek	GU	Guadalupe	TE	Tempe
CH	Chandler	LP	Litchfield Park	TO	Tolleson
CO	County	ME	Mesa	WI	Wickenburg
EL	El Mirage	PV	Paradise Valley	YO	Youngtown
FH	Fountain Hills	PE	Peoria		
GB	Gila Bend	PH	Phoenix		

Field Name: **CITY**
Field Type: character
Field Size: 15
Source: MetroScan or original MAG Parcel Database

Description

City is the mail city associated with the mailing address of the parcel, if given. This can differ from "City Code" (previous page) when jurisdictional and post office designation for a jurisdiction are different.

City

Avondale	Gilbert	Phoenix
Buckeye	Glendale	Queen Creek
Carefree	Goodyear	Scottsdale
Cave Creek	Guadalupe	Surprise
Chandler	Litchfield Park	Tempe
El Mirage	Mesa	Tolleson
Fountain Hills	Paradise Valley	Wickenburg
Gila Bend	Peoria	Youngtown

Field Name: **CENBLK**
Field Type: character
Field Size: 4
Source: MetroScan

Description

This is the Census Block number in which the parcel is located. This number is only unique within a particular Census Tract. This information is typically only filled for residential parcels with site addresses.

Field Name: **CENTRCT**
Field Type: character
Field Size: 6
Source: MetroScan

Description

This is the Census Tract number in which the parcel is located. This information is typically only filled for residential parcels with site addresses.

Field Name: **CONDITION**
Field Type: character
Field Size: 15
Source: MetroScan

Description

This field describes how the condition of the improvement on the parcel compares with the norm for improvements of the same type and grade. Common descriptions used include:

Condition
Below Average
Average
Above Average

Field Name: **EXAMT**
Field Type: Real
Field Width: 15
Field Format: F15.2
Source: MetroScan

Description

This field contains the portion of full cash value exempted from property tax.

Field Name: **EXCODE**
Field Type: character
Field Size: 15
Source: MetroScan

Description

This field describes the nature of the property tax exemption, if any. Common exemptions include:

Exemptions

Historical
Veteran

Field Name: **LCIC**
Field Type: character
Field Size: 4
Source: MetroScan

Description

The LCIC (land class, improvement class) code is also known as the property use code. This code indicates the predominant use of the parcel and information about the type of structure (if any) that exists on the parcel. A very brief outline of the LCIC code system is shown below.

<u>LCIC</u>	<u>Property Use</u>
0000-0085	Vacant Land
0100-0198	Single Family Residential
0300-0380	Multiple Residential
0400-0600	Hotel-Motel-Resort
0700-0770	Condominiums
0800-0870	Mobile Homes
0900-0950	Miscellaneous and Salvage
1000-2900	Commercial Property
3000-3740	Industrial Property
4000-4910	Ranch Property
5100-5900	Public Utilities
6100-6900	Natural Resources
8500-8900	Special Use Property
9200-9860	General Service Use

The first two numbers in the code indicate the basic classification of vacant, residential, commercial, industrial, etc. The last two numbers of the code identify additional characteristics and major subcategories of property uses. A complete listing of code can be obtained from the County Assessor's Office.

Field Name: **LANDFCV**
Field Type: real
Field Width: 15
Field Size: F15.2
Source: MetroScan

Description

This field contains the full cash value of the land in the parcel. It is expressed in dollars.

Field Name: **MAGLU**
Field Type: integer
Field Size: 2
Source: MetroScan

Description

The MAG land use code is a one or two number code used to indicate the use of the parcel. This code is similar to but much more general than the LCIC code. A description of the codes are listed below. the nature of the property tax exemption, if any. Exemptions include:

<u>Code</u>	<u>Description</u>	<u>Code</u>	<u>Description</u>
01	Residential Single Family	14	Medical Services Nursing Homes
02	Townhouse	15	Hospitals and Clinics
03	Multifamily	16	Medical Offices
04	Mobile Home		Industrial
	Hotel/Motel	17	Manufacturing
05	Hotel/Motel	18	Warehouse
06	Resorts	19	Public Utilities
	Commercial (Retail)		Public/Quasi Public
07	Neighborhood Retail	20	Schools
08	Community Retail	21	Government
09	Regional Retail	22	Churches
10	Strip Commercial		Vacant/Low Density
11	Auto Service/Sales	23	Vacant Developable
	Office	24	Vacant Non-Developable
12	Small Offices	25	Golf Courses
13	Large Offices	26	Mining
		27	Under Construction
		28	Other Miscellaneous

Field Name: **PAGEGRID**
Field Type: character
Field Size: 8
Source: MetroScan

Description

PageGrid is reference to a page in the mapping system used by MetroScan. It is usually only filled in cases where address and/or Census tract and block are also filled in.

Field Name: **PARCEL**
Field Type: character
Field Size: 9
Source: MetroScan

Description

The 9 character parcel field is comprised of 4 subsets of data:

- | | |
|-----------------------------|------------------------|
| 1) assessor's book number | 3 characters |
| 2) assessor's map number | 2 characters |
| 3) assessor's parcel number | 3 characters |
| 4) assessor's split | 1 character (optional) |

The PARCEL is a unique identification number for a property and can be used to locate a property on the assessor's maps. An example PARCEL number is:

10107024A
(book 101, map 07, parcel 024, split A)

Since the split portion of the PARCEL is optional the last space of this field may be blank.

Field Name: **QUALITY**
Field Type: character
Field Size: 15
Source: MetroScan

Description

This field, derived from the Residential Master File, indicates the grade of the materials and quality of workmanship of a parcel improvements. The QUALITY descriptions are as follows:

<u>Quality</u>	minimum
	fair
	good
	excellent

Field Name: **ROOMS**
Field Type: integer
Field Size: 6
Source: MetroScan

Description

This field, derived from the Residential Master File, indicates the number of rooms in a residential structure. It includes only major living areas such as the kitchen, living room, dining room, and bedrooms. Bathrooms, storage rooms, garages, and rooms not separated by a wall are not included in the room count.

Field Name: **SALEDATE**
Field Type: character
Field Size: 6
Source: MetroScan

Description

The sales date corresponds to the filing date of the deed. The format for the sales date is year-month-day, for example, November 16, 1993 would appear as 931116.

Field Name: **SALEPRICE**
Field Type: real
Field Width: 15
Field Size: F15.2
Source: MetroScan

Description

The sales price is included for the most recent sale. The sales price originates from the affidavit of value. Occasionally, the sale will not be an "arms length" transaction and therefore will not represent the true market value of the property. The sales price is stored as a real number and is in current dollars as of the SALEDATE.

Field Name: **SQFTEARLY**
Field Type: real
Field Width: 10
Field Size: F10.0
Source: MetroScan

Description

This field indicates the square feet of the improvements from the earliest construction year for the parcel. See YEAREARLY for the corresponding year of construction.

Field Name: **SQFTLATE**
Field Type: real
Field Width: 10
Field Size: F10.0
Source: MetroScan

Description

This field indicates the square feet of the improvements from the latest construction year for the parcel. See YEARLATE for the corresponding year of construction.

Field Name: **SQFTMOST**
Field Type: real
Field Width: 10
Field Size: F10.0
Source: MetroScan

Description

This field indicates the square feet of the improvements from the year with the most construction on the parcel. See YEARMOST for the corresponding year of construction.

Field Name: **SQFTTOTAL**
Field Type: real
Field Width: 10
Field Size: F10.0
Source: MetroScan

Description

This field indicates the total square feet of the improvements on the parcel.

Field Name: **STORIES**
Field Type: integer
Field Width: 6
Field Size: I2
Source: MetroScan

Description

The number of stories is designated for residential parcels using the numeric code listed below:

<u>Story Code</u>	<u>Description</u>
10	1 story
15	1 1/2 stories
20	2 story
25	2 1/2 stories
30	3 story
40	4 story

Field Name: **TAXAREA**
Field Type: character
Field Size: 6
Source: MetroScan

Description

The tax area code indicates the school district, city, and improvement district within which the parcel is located. The tax area code identifies the tax rates applicable to the assessed value of the parcel. The first two characters of TAXAREA are the school district, and the last two characters are the city/special district. Tax code are currently numbers from 0000 through 9890. All codes currently contain four number so that the effective field width is 4 characters. However, there is discussion of adding two additional characters to distinguish between city and special districts, thus a field width of 6 characters is allocated.

Field Name: **TAZ 1272**
Field Type: character
Field Size: 4
Source: Mountain West / MAG

Description

TAZ 1272 shows the TAZ (Traffic Analysis Zone) within which the parcel is located, according to MAG's 1272 zone system used from approximately 1988 through 1990. These number were transferred to the updated Parcel Database of the purposes of historical analysis. The TAZ's were assigned by a computer program and may not be accurate in all cases.

Field Name: **TAZ90**
Field Type: character
Field Size: 4
Source: MAG / GIS Southwest

Description

TAZ90 shows the TAZ (Traffic Analysis Zone) within which the parcel is located, according to MAG's current (December, 1993) zone system. The TAZ's are numbered from 1 to 1390. The TAZ's were assigned by a computer program, using the x,y coordinates of the parcel derived from addresses and book-map centroids and may not be accurate in all cases. However, the accuracy of these TAZ numbers should be better than those found in TAZ 1272.

Field Name: **TOTUNITS**
Field Type: integer
Field Size: 6
Source: MetroScan

Description

TOTUNITS contains the total number of housing units located on each residential parcel.

Field Name: **X_IN**
Field Type: real
Field Width: 10
Field Format: F10.2
Source: MAG / Mountain West

Description

X_IN contains the x-coordinate of the parcel as assigned in the development of the original Parcel Database. These coordinates were assigned by the LandTrak system, and are expressed in Western State Plane Coordinates. This information was carried over to the updated Parcel Database because it can be converted and compared with new x-coordinates assigned by Arc/Info (X_COORD).

Field Name: **X_COORD**
Field Type: real
Field Width: 10
Field Format: F10.2
Source: MAG / GIS Southwest

Description

X_COORD contains the x-coordinate of the parcel as assigned in the process of updating of the Parcel Database. These coordinates were assigned either by address matching using MAG's "MAGNET" street database, or using the digitized centroid of the parcel's Book-Map. The XYFLAG field indicates the method used for that particular parcel. X_COORD was assigned using Arc/Info, and is expressed in Arizona Central State Plane Coordinates.

Field Name: **XYFLAG**
Field Type: character
Field Size: 2
Source: MAG / GIS Southwest / ESG

Description

The XYFLAG indicates the way in which the X and Y coordinates contained in X_COORD and Y_COORD were assigned in updating the Parcel Database. All XY coordinates were assigned one of two ways. About 50 percent were addressed matched against MAG's "MAGNET" street network, and have an XYFLAG of "AD". The other half were assigned using the centroid of the Book-Map the parcel is contained within. These XYFLAG on these parcels is "BM".

Field Name: **Y_IN**
Field Type: real
Field Width: 10
Field Format: F10.2
Source: MAG / Mountain West

Description

Y_IN contains the y-coordinate of the parcel as assigned in the development of the original Parcel Database. These coordinates were assigned by the LandTrak system, and are expressed in Western State Plane Coordinates. This information was carried over to the updated Parcel Database because it can be converted and compared with new y-coordinates assigned by Arc/Info (Y_COORD).

Field Name: **Y_COORD**
Field Type: real
Field Width: 10
Field Format: F10.2
Source: MAG / GIS Southwest

Description

Y_COORD contains the y-coordinate of the parcel as assigned in the process of updating of the Parcel Database. These coordinates were assigned either by address matching using MAG's "MAGNET" street database, or using the digitized centroid of the parcel's Book-Map. The XYFLAG field indicates the method used for that particular parcel. Y_COORD was assigned using Arc/Info, and is expressed in Arizona Central State Plane Coordinates.

Field Name: **YEAREARLY**
Field Type: integer
Field Size: 4
Source: MetroScan

Description

This field indicates the year that the first construction occurred on the parcel. It is expressed as four digits, for example, 1983. See SQFTEARLY for the square footage constructed in this year.

Field Name: **YEARLATE**
Field Type: integer
Field Size: 4
Source: MetroScan

Description

This field indicates the year that the last construction occurred on the parcel. It is expressed as four digits, for example, 1983. See SQFTLATE for the square footage constructed in this year.

Field Name: **YEARMOST**
Field Type: integer
Field Size: 4
Source: MetroScan

Description

This field indicates the year that most of the construction occurred on the parcel. It is expressed as four digits, for example, 1983. See SQFTMOST for the square footage constructed in this year.

Field Name: **ZIPCODE**
Field Type: character
Field Size: 6
Source: MetroScan

Description

This field indicates the ZIPCODE that the parcel is within. This is generally only filled in when a valid site address was available.

REDEVELOPMENT “FOOTPRINTS”

**MARICOPA ASSOCIATION OF GOVERNMENTS
SOCIOECONOMIC MODELS ENHANCEMENT PROJECT
REDEVELOPMENT DATABASE MAP**

The map displays a complex network of streets and land parcels. Key streets include Highway 60 running horizontally across the top, and several vertical roads such as Valley Road, Phoenix Park Road, and others. Many parcels are marked with numbers (e.g., 1, 2, 3, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100) and some are shaded with diagonal hatching. A scale bar at the bottom indicates distances from 0 to 100 feet.
